—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

Hooker's Patent Direct Acting Steam Pump.

W. T. GARRATT,
Cor. Fremont & Natoma
streets, S. F.,
Sole Proprietor & Manu-
facturer for the Pacific
Coast.

**SIMPLE, CHEAP AND
DURABLE.**

Adapted for all pur-
poses for which Steam
Pumps are used.
The Best Pump in Use.

SEND FOR CIRCULAR

N. B.—Also manufacturer of Hooker's Deep Well and Double-Acting Force Pump. Received the Silver Medal awarded at the last Mechanics' Fair in San Francisco.

THE MINING AND SCIENTIFIC PRESS is one of the best papers published on this coast. It should be in the hands of every miner and mechanic in the State. The issue of last week contained an excellent article on the old product of this coast.—Oroville Mercury, Jan. 28.

ANGELL'S CHARCOAL DENTAL SOAP
for Whitening and Pre-
serving the Teeth, J. W. ANGELL, Prop., San Francisco.

TULLOCH'S AUTOMATIC ORE FEEDERS

Increase the Capacity of each Battery Two to Three Tons per day.

**SAVE LABOR! SAVE MORE GOLD!
SAVE SHOES AND DIES.**

One Man Can Attend to a Hundred Stamps.

**WILL FEED ANY KIND OF ORE,
WET OR DRY.**

ARE DIRECT ACTING. EACH MOTION SCRAPES A POR-
TION OF THE ORE INTO THE BATTERY. CAN
REGULATE THE FEED. ARE SIMPLE AND
DURABLE. ARE IN USE IN CALI-
FORNIA, NEVADA, IDAHO AND
MEXICO. WARRANTED
TO WORK.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustio and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

Richards, London & Kelley's
BAND SAW.

SMITH'S PATENT
POWER
MORTISERS.

Mortiser.

WITH
LATE
IMPORTANT
IMPROVEMENTS.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"P," "Q," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. BERRY & PLACE, Selling Agents.

NOTICE.

A Quartz Mine and Mill For Sale.

The Mill containing one five stamp battery, free water power. Sample of rock from the Mine can be seen at the MINING AND SCIENTIFIC PRESS office, San Francisco. Location: Oregon Gulch, near Croville, Butte county, Cal.

About thirty or forty tons of Quartz are already out and every day am taking out more.

A. GRUMMET.

PAUL'S DRY PROCESS.

An effective, cheap and practical way of obtaining the highest percentage of Gold and Silver at the least expense. For plans, pamphlets, or particulars, apply to

ALMARIN B. PAUL,
Room 20, Safe Deposit Building.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867. The most complete treatise. Published at this office. Price \$5, post-paid.

A Caution to the Public.

The following paragraph appeared in the *Stock Exchange*, April 12th:

"The Jenny Glynn Gold and Silver Mining Company propose to increase its capital stock from twenty thousand shares of the par value of twenty-five dollars each, to one hundred thousand shares of the value of fifty dollars each. The mine is now being worked by the Fryer process, and the most satisfactory results are being looked for soon. The increase of shares will be voted upon on the 17th day of April, and will give five new for one old share."

We cannot but feel gratified by any expression of confidence in the Fryer Process, yet it is due to the public that we should say that we have not made any arrangement with the Jenny Glynn Gold and Silver Mining Company, or with any other company, for the use of our Process for the reduction of refractory ores. No person is authorized to say or do anything for us and in our name, save those who are associated with us and bear our written authority.

ENRIGHT'S PATENT PORTABLE

Wood and Straw-Burning Engines.

Patented July 20th and November 2d, 1875.

Burns Wood or Straw without change, and Coal by changing two plates. Took the Premium at the California State Fair, 1875, as the Best Straw-Burner.

Pioneer Builder of the First Portable Thresher Engine on the Pacific Coast, 1861.

PATENTEE AND BUILDER

OF THE

Best Portable Straw or Wood Burning Thresher Engines, 1876.

Send for Testimonials and Price to

JOSEPH ENRIGHT, San Jose, Cal.

SHERIFF'S OFFICE, SACRAMENTO, Sept. 21, 1875.

MR. J. ENRIGHT—Dear Sir: The Straw Burning Engine I bought of you, and which was used in Yolo County, has given us perfect satisfaction. It is everything you represented. We have had no difficulty in generating all the steam required, and the amount of straw consumed can hardly be misused. We find it much safer, on account of fire, than a wood-burner. Many persons, both there and farmers, have come to see it run, and all express themselves highly pleased. The opinion of all was, that it is just what we need, being safe and economical.

H. M. LARUE.

The Buckminster Rock Drill.

This drill, one of the latest introduced in the market, has been designed with a view of remedying certain defects of construction and operation which have to a great extent heretofore rendered rock drilling engines unreliable and expensive, both as regards original cost and cost of repairs. We give on this page two illustrations of this drill, one showing it mounted on the tripod and the other showing it on a column for tunnel work.

The Buckminster drill is of the simplest construction possible consistent with efficiency of action, there being no exterior machinery liable to injury from rough usage, all the working parts being enclosed within the cylinder and valve chest. These working parts are few and simple in their arrangement, so that the liability to become injured from accident or ordinary wear and tear is reduced to a minimum. On this drill the most prominent improvements are on the turning and valve movements, and also on the three different clamps. One of these clamps is for holding the drill on the tripod; another is for holding the drill tool in position; and the third is for holding the weights upon the legs of the tripod.

It is unnecessary to describe the details of mechanical construction of those parts which are common to all drills, so we only allude to those which are new and improved. The device for turning the valve is simple. The valve is what is known as the "double D" valve, moving parallel with the axis of the cylinder, and is similar to that applied to ordinary steam engines. To operate this valve a simple and ingenious device is applied. This consists of a lever standing vertically and swinging on a center pivot conveniently secured through the sides of the valve chest. The upper end of this lever is inserted in a slotted hole in the arch of the valve, whilst the lower end of the lever is formed into two cam shaped ends, each working in a slotted way provided for it, in a sleeve piece which fits loosely upon the piston rod between the two piston heads. These slotted ways have three bottom surfaces, slightly inclined for their entire length, and at one end of each slot a sudden rise of the inclined bottom ends the slot entirely, so that the lever whose lower cam-shaped end rests on the bottom of one of the slots is vibrated as the piston moves, and with it the valve is thrown and each end of the cylinder supplied with air alternately.

There are no parts of this device liable to sudden shock or excessive friction, the valve is not more suddenly moved than is desirable, and it is never at rest except when the drill is stopped, so that it is impossible for the valve to stick or clog.

The most important feature of this drill is the device for rotating the drill so as to present the cutting faces in a different position at each blow. This consists in simply cutting the sleeve piece before mentioned into two pieces by a zigzag cut and providing a slot in one-half of the sleeve, in which a lug, fastened in the side of the cylinder, may play back and forth as the piston moves, the slot having a slight twist, as in a rifle. Now, as the piston moves in one direction the sleeve piece turns loosely between the heads of the piston and no effect is produced upon the drill, but when moved in the opposite direction the two parts of the sleeve spread apart, owing to the inclined surface of the cut, and the sleeve being now tightly wedged between the piston heads, which are fast on the piston rod to which the drill is clamped, when the sleeve is rotated (as it will be on account of the pin or lug before mentioned working in the slot,) necessarily the drill will rotate with it, the degree of rotation depending upon the amount of twist given the slot in the sleeve.

This device is extremely simple, there being no extra pieces excepting the pin; there is no possibility of the parts getting out of order; there is no chance for wear, and the motion is positive and never fails of action.

One of the clamps which is improved is that for holding the sliding ways of the drill to its column in the tripod. This clamp is so con-

structed that the drill carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp. The clamp is made with a hinge and hinged bolt, and has a sliding wedge, being so constructed that in turning upon this hinged bolt the clamp is made rigid on the carriage, and also clamped rigidly in the column.

Another improved clamp is that which holds the weights on the legs of the tripod. Usually these weights are secured with a key or screw. In this case an eccentric with handle is used, so that when the weight is moved up or down, the eccentric relieves it or secures it by a simple quick movement.

The manufacturers claim that the amount of work which these drills are capable of performing will be found far in excess of that ordinarily accomplished, while the hole is always perfectly true and smooth, so that the full area due to the size of the drill is always obtained, and thus the power of the blast proportionately increased. The economy of this drill in the

matter of the expenditure of power is a marked feature. It is asserted that three of these drills can be run with the power required to move four ordinary drills. In the matter of

fitting and workmanship, the fact is recognized that no kind of machinery is subject to such a strain as that employed in rock drilling, and no pains and expense has been spared to make this machine as near perfect as possible. The parts subject to wear are all made of the best tempered cast steel, giving it the greatest strength with lightness and portability. All the parts are made to gauge and made interchangeable with those of any other machine of the same size. A very important point in this machine, and one that will be appreciated by min-

ing men, is that the drill is very light. It is almost entirely steel, which admits of great facility of handling and all superfluous weight of metal is dispensed with. After handling some of the ponderous machine drills now in use, this one seems nothing at all to move about.

THE BUCKMINSTER DRILL ON TRIPOD.

THE BUCKMINSTER DRILL ON COLUMN.

These drills, though working to a greater advantage with compressed air, may also be operated by steam. The sizes of the holes which the machine is capable of drilling are from half-inch up to five inches in diameter, and any depth up to 40 feet. The rate of drilling of course varies with the quality of rock—easy, ordinarily, eight inches per minute as an average. The number of blows delivered varies according to the size of the machine, 250 to 300 blows per minute being the ordinary speed of a three inch machine.

These drills are now being made at the Pacific iron works, First and Fremont streets, in this city. They also manufacture an air compressor which has several new devices. It is a remarkably compact, simple and efficient machine, and is light and more easily handled than an ordinary compressor. The compression of air is attained with much less than the usual loss by friction, and with a small expenditure of power.

Another New Process.

We have to announce the advent of another new process for extracting the precious metals, which is the idea of Mr. Benjamin J. Harrison, of Santa Rosa, Sonoma county, California. This gentleman called on us recently, and without explaining the details of his invention, told us what he could do with it and about the experiments he had made. He has promised to send us samples of the rock before and after treatment, so that mining men can examine it.

Mr. Harrison says he takes the sulphurets after the rock is crushed and reduces them to a form by which the gold can be extracted easily, or rather, he destroys them entirely and leaves the metal perfectly free. The process is introduced between the crushing and amalgamating as usually practiced. It is intended more particularly for highly sulphureted rock. When there is any lead in the rock it is saved or thrown aside as desired. It is saved entirely separate from the gold, and in a metallic form in little lumps.

From this residue of sulphurets a paint can be made, which the inventor claims will pay all the expenses of the process. This residue is from the sulphurets themselves and is reduced to another form to make the paint, which is saved or not as desired. This process has been tried experimentally, and further experiments are now being made with it.

For a 12-stamp mill the necessary machinery for the introduction of this method of working sulphurets will cost about \$1,500, including chemicals and everything. The expense of operating it will be about the same as the cost of crushing. The claim for this process is quickness, cheapness and effectiveness. The inventor says it will simplify the amalgamation very materially. We are unable to say anything about the details of this process, simply because we are ignorant of them. For the same reason we are unable to say whether there is "anything in it" or not; but are promised the result of the experiments now being made on a practical scale as soon as they are concluded. We will then speak of the matter again.

ESTIMATES.—An old Utah miner, who professes to be familiar with the present condition of all the mining camps in the Territory, estimates the yield for 1876 as follows: Bingham, \$3,000,000; Alta, \$3,000,000; Park City, \$2,000,000; Dry Canon, \$1,000,000; East Canon, \$750,000; Stockton, \$400,000; Tintic, Camp Floyd, Beaver and the Southern Utah districts, \$1,000,000—making a total of \$11,150,000. We have no means of knowing anything of the correctness of these estimates, but they appear pretty large. It is beyond the power of any man to make very accurate estimates of future mining yields, and such statements carry very little weight.

TWENTY-THREE sacks of Gladiator ore, from Boulder, Colorado, were recently sold in Golden at the rate of \$4,000 a ton, the highest price paid for samples of the lot being \$8,000 per ton.

The antimony mines at San Emidio, Kern county, are turning out three and a half tons of crude antimony per day.

CORRESPONDENCE.

Botanical Excursions.

[By J. G. LEMMON.]

No. 2. The Northern Valleys and Lassen's Peak. (Continued.) Part II. Butterfly Valley and the Darlingtonia.

Butterfly valley is a small out-lying dell in the high forest six miles northwest of Quincy. It must be peculiarly situated, and its origin as singular, for it is endowed with the greatest variety of rare, radiant and curious plants of any locality of its size met with thus far in all my exploration of the Sierra. This valley is most intimately related to all my labors, aspirations and achievements—such as they are—for the last five years. The course and aims of my life were so changed by a discovery made here that I beg the reader's indulgence while I narrate.

In Black Hawk ravine, a mining camp near here, while following the business of book selling, five years ago, I found in an almanac a small leaf of a plant most interesting in appearance and which I recognized as belonging to the *Sarcocolla* order, but O, so different from anything ever seen before! All the latent botany of my being—repressed for a lifetime because there was no money in it—was aroused beyond control. I demanded its origin. No one could tell. I ran from house to house. No one knew the place of its growth. At last I betought me of the children—those natural conservators of such facts—and asked the first group met. "I know," said little Mamie Austin, "Uncle Rice brought it down from Butterfly." Here was light. Arrangements were made to have Uncle Rice meet me there two months from that day and guide me to Butterfly and the secret ravine where grew this curious plant. Before the time arrived, as I continued my long trips, I displayed the treasured leaf freely, and at the day agreed upon for the search I met at Black Hawk four persons, with whom I was subsequently to form the most sincere and enduring friendship—Mr. and Mrs. Moser, of American valley, and Mr. and Mrs. Ames, of Indian valley, the last the excellent lady and botanist so often mentioned and honored since by Drs. Gray, Canby and Thurber.

Our hostess at Black Hawk, Mrs. Austin, with her children, also joined the exploring party. This lady, with her husband and family, soon after bought the wonderful Butterfly valley and removed to its Eden garden, where she and Mrs. Maxwell, residing in Glendale, just below, have since done most important botanical work, requiring the expenditure of much time and the closest scrutiny day after day, during season after season.

It was quite a cavalcade, that exploring party. The ladies and children were on horseback, the gents on foot, with the good souled Uncle Rice in the advance, all toiling up the steep mountain trail, tearing through bushes and plowing across streams, but the view that awaited repaid all. Our guide cunningly led the way as if to pass the object. "O, look! There they are!" shouted Mrs. Ames, pointing down toward a small round meadow, bordered with alder bushes, through a gap in which appeared the most wonderful plants to be seen north of tropical America. Every eye was fixed; every throat gave a single exclamation of delight that formed a strange chorus. The ladies and children were quickly helped to the ground and all together ran down to the alders. There, thickly covering a space of a fourth of an acre within the alders, stood the round, tubular, swollen stalks, surmounted with balloon-like scarlet hoods, with dependent, curled, crimson, mustache-like wings, all constituting the insect-catching leaves of the

Darlingtonia Californica.

What a feast followed! How the children ran to pluck and bring leaves to be compared and admired! How we revelled and wondered! Mr. and Mrs. Ames gathered a mass of specimens to be studied at leisure in their quiet home. Mrs. Austin sat down by a splendid plant and at once commenced the close scrutiny which she has continued to give the living plant so many weeks and months since. Some 11 patches of *Darlingtonia* she has found in and around Butterfly, generally clustered around cool springs on a southern slope and at an elevation of about 4,000 to 5,000 feet. Another insect-devouring plant grows in the same bogs with it, the *Drosera rotundifolia*; and on both of these plants Mrs. Austin has bestowed observation and experiment that will be read with interest in lands beyond the sea, for she is as good at noting and reporting as at experimenting.

Observations on Darlingtonia.

Dr. Canby, of Wilmington, Del., wrote, asking 32 questions, and Dr. Gray a long list more, relating to this wonderful plant, its structure, how and what it catches, and what for. Such is the interest manifested, that it will not be strange if one of these eminent scientists, or even the renowned Darwin himself, should visit Butterfly valley in the near future, and there institute those chemical experiments and microscopic observations that determine the law of development by adaptation, which in scarcely any other plant is more beautifully and distinctly illustrated than in *Darlingtonia*.

Fortunately Prof. Bessuy and others have lately, through the columns of the Press, familiarized your readers with the structure (illustrated though with engravings grossly at fault, and which the accompanying photograph may serve to correct), habits and appearance of this carnivora, so I will only add a few important facts, indistinctly derived from dried specimens sent him by me, and reported by Dr. Canby before the American Academy of Sciences, but now abundantly verified by observations on the living plant by Mrs. Austin and myself.

1. The infant leaves. Each season produces a whorl of four leaves, in infancy very different from the leaves on older rhizomae—tubular, open-mouthed, with a long, slender, crimson projection of the mid-rib of the petiole, beyond the large mouth, instead of the hood with the small covered aperture and "mustache" of older plant leaves. This curious departure from the true *Darlingtonia* leaf is sometimes found upon small off-sets, mixed with the other leaves, and affords an argument for the development theory, being evidently vestiges of a change this plant has undergone from the open-mouthed, simple-leaved *Sarcocolla* to this carefully concealed trap and decoy of the *Darlingtonia*.

2. The twisting leaves. The leaves of mature rhizomae are each twisted one-half of a turn round, whatever the length, whether but a half inch or three feet. All the leaves on one plant turn one way, but exactly half of the plants have leaves turning one way, the other half the other way. The four leaf stalks rise to different elevations, the last of the season the highest. Each holds its head outward, i. e., presents its brilliant mustache and entrapping hood facing outward from the center or axis of the plant—evidently with the design of enticing and snaring insects coming from any direction.

3. The alluring sweets. A saccharine fluid of the consistency of honey is secreted by the glands of the hood both without and within, standing in beads along the margins of the expanded cells forming the translucent hoods, and often so abundant as to unite and run down, that on the inside into the forward depression of the hood, that on the outside smearing the mustaches completely, in addition to a similar secretion of the latter.

4. The drowning wells. A water-like fluid is secreted by glands on the inner surface of the tubular petiole, or leaf stalk, which begins to appear at the bottom the very day that the orifice begins to open in the hood above. This fluid continues to accumulate as long as the catching season lasts, is always sufficient to cover the mass of insects, and where the trap is so favorably situated as to catch its stomach full, or when fed to the top, as has often been done, slowly, the fluid will still rise to the necessities of the times, and fill the tube to overflowing.

Why this Deadly Trap?

A most puzzling question. Of course, to catch insects; but why to catch them? What for? While watching the movements of a swarm of insects, hovering over a patch of *Darlingtonia*, this season, I took a bit—a mere fancy, to be sure, but if the flowering season continued through the summer, there would be a color of reason in it. I fancied I detected the operation of a law that rises into the realm of morals and endows these plants ever after with a new interest to me. The operation is no less than the astounding spectacle of a penalty—a death penalty—inflicted by the vegetable kingdom upon the animal, for the sin of disobedience.

Fertilization.

This hint was connected with the fertilization of the plant. Let us glance at the process in detail: The single large flower of the *Darlingtonia*, elevated on a tall scape, from a few inches to two feet above the hooded leaves, is turned downward, at the time of first opening, like a bell; afterward it unbends and becomes erect. While downward the flower expands, the pollen is discharged and the ovules fertilized; but at a first glance it seems impossible as the essential organs are disposed. The five pistils in the center curve outward and upward, bringing their stigmas into the apex of the bell, wherein nectaries are stored the choicest sweets. The five stamens extend downward along the distended petals, holding at arm's length their anthers; a long distance below the stigmas. Now, how will the grains of pollen, discharged from the anthers, get up to the stigmas, else the ovules will not be fertilized—will not mature? See! Here are oval apertures formed by opposed notches in the sides of the crimson petals, through which on five sides you observe the flaming yellow, green and purple sepals, colored and curled so as to form attractive objects from any direction.

Insect Agency.

The flying insect disporting himself among the flowers for the few brief hours of his existence, has an important mission of usefulness to perform in the economy of nature, until of late totally unsuspected.

Always attracted to bright objects—as the moth to the candle, the humming bird to the artificial flower—the flying insect spies in the distance a most fascinating object. As he flies towards it his olfactory organs are greeted by delicious odors, increasing his speed. Alighting momentarily upon the flaming floral envelopes, he finds the increased fragrance issuing from the openings. Immediately he enters, climbs up to the nectaries, but on the way crowds against the partially obstructing anthers and carries a back-load of adhering pollen grains up and presses them against the viscid stigmas,

while diving to his shoulders in the jar of sweets—and thus the flower is fertilized, thus the plant continues to bear fruit year after year, thus the tiny insect is made subservient to use, designed and appointed from the beginning.

Vegetable Vengeance.

Failing to do this (and here is where the fancy spoken of comes in), too heedless of the inborn dictates of duty, or foolishly suspicious of danger in entering a dark flower, the poor creature mauls on in the world exposed himself to destruction by other animals, or starves to death; but in the case of the *Darlingtonia* the neglected flower is avenged (if I may be allowed to use the word) by the cunning leaf of the same plant.

Missing the apertures in the flower, or sheering off from suspicion, yet wheeling round and settling in his flight, he sees the daunting lure of the mustache below, alights upon the very innocent looking hood, feeds upon the sweet and no doubt intoxicating secretion, enters the opening beneath—the thin membrane of the upper surface of the hood fully admitting the light, so he sees his way clear, journeys on over the honey pastures, gorging himself with sweets, passes easily the boundary rim so difficult to retrace, slips on the glassy neck of the tube, falls into the pit, struggles against the downward projecting hairs, dives into the water and is drowned—as he deserves!

His carcass is fed upon by the larvae of other insects in waiting, and no doubt the choicest bits are assimilated into the plant, forming the incentive agents, the sinews of war for the destruction of all of his kind.

The Peavine Refractory Ores.

EMERSON PRESS:—The ores of the Peavine district have been long known to be rich in silver, but have hitherto proved too refractory for profitable work by any known process. The chemical compounds are so complicated, each one holding so tenaciously to its portion of silver, and only releasing it, perhaps, to form some equally difficult combination—that new obstacles to a proper reduction of the ore have constantly arisen to take the place of those which were vanquished. The owners of the mines have tried probably all the methods in use on this coast, and have spent a great deal of money in their experiments without any satisfactory results until now. But at this date some of them are much encouraged by the working of the O'Hara furnace and the developments of the Fryer process. The former is in use by the Poe Consolidated company, at the Paymaster mine. This company put up a mill in 1873 to work their ore by wet crushing, but failing to get any result by this method, it was determined to try a furnace process, and in the winter of 1874-5 the furnace known as the McGlan patent was put up and the mill changed from a wet to a dry crusher.

As this furnace had succeeded well with other ores, high hopes were entertained of its success here. But these were doomed to disappointment, and it was rejected after a brief trial. In the spring of 1875 a contract was made with D. J. O'Hara to put up one of his furnaces. This also was beaten by this rebellious ore, but there being encouraging indications that it would succeed with some changes in the manner of working, another trial was made with a furnace of increased capacity. In a short time the managers expressed themselves satisfied that the furnace would do their work. It was therefore accepted and paid for and is now in operation. They certainly deserve to succeed in view of the pluck and determination exhibited, having expended in works and tests over \$150,000 without, until now, any returns. For the past ten days the furnace has been working steadily with a continued improvement in the quantity and quality of bullion produced, and they now believe that they have an assured future. Another company, whose mine is in this district, the Golden Fleece gold and silver mining company, have had to exercise much patience and resort to long and tedious investigations in their efforts to have their ore worked. They began work in October, 1873, by running a tunnel 910 feet, and struck the ledge at 460 feet from the mouth of the tunnel. From this point an incline was run 82 feet, all the way in ore of about the same quality, and an air shaft was raised 112 feet to the surface, so constructed as to be used also for hoisting. The remaining 450 feet of the tunnel continues in ore of good quality. The whole is substantially timbered; thus being prepared for active operations whenever they should find a satisfactory method of reducing their ore. After numerous tests, extending over several years' time, they determined that the Fryer process gave the best results and that they would patiently wait until the company was ready to put up the works. The test by the Fryer process upon which they principally relied, was one of 18 pounds of their worst (most rebellious) ore, which gave 8 dwts. of silver, 940 fine, and a fractional quantity of gold, the assay value per ton being \$54.60, of which \$9.18 was gold. Their patience and faith are now about to be rewarded, having contracted with the Fryer company for the construction of the first works which will be put up for any one. One of the Messrs. Fryer visited this mine a few days since, when the agreement was consummated, and it is expected that

the furnace will be in operation in two months from this date. As the company has about 3,000 tons of ore on the dump and in the ore house, they expect to have no delay in the production of bullion when the furnace is ready.

There are numerous other claims in the Peavine district on which more or less work has been done, but the owners are waiting for and profiting by the experience which shall teach them the best methods of working these difficult ores.

The mining interests of the Washoe country have the prospect of being further increased by recent discoveries of quicksilver. If the agricultural resources of this valley are to be supplemented by a full development of the mineral wealth of the hills which surround it, Reno is destined to become a city of size and importance.

Reno, Nevada, April 17th, 1876.

The Glaciarium.

A very interesting account of a novel arrangement comes to us in *Engineering*, by which John Gamgee has succeeded in maintaining an artificial skating rink in Chelsea. It is called the "Glaciarium." We condense from *Engineering* an account of the affair, partially because Mr. Gamgee has succeeded in producing an artificial skating ground where many others have failed, but chiefly because his process involves a new method of ice making which may prove valuable in producing ice for the mouth as well as the feet. In designing the skating rink at Chelsea, Mr. Gamgee originally proposed to have a floor of iron plates carried on transverse girders of the same metal, which were laid on wood bedded on concrete, the refrigerating liquid flowing through the spaces thus formed. This was in 1874, but in practice Mr. Gamgee considerably modified his notion of laying a system of cast iron pipes of rectangular section connected on a bed of concrete, and grouting them with cement. In the case of the Glaciarium the concrete bed is 24 feet long by 16 feet wide, giving only a comparatively small rink of about 43 square yards area; but then it is an experimental rink. Around the concrete is a raised ledge forming a trough containing water to be congealed, which is about 2 inches deep, and which surrounds three sides of each of the pipes. In selecting the liquid for producing congelation, Mr. Gamgee discarded the use of brine for the reason that saline solutions act destructively on metallic surfaces from galvanic and chemical causes. Besides, such media are themselves liable to congelation if exposed to too low a temperature, or if the circulation be sluggish, so that a fatal obstruction might be caused. He therefore uses as a cold transmitting liquid a mixture of glycerine and water, which remains uncongealed at a temperature below zero. This liquid is pumped up at starting from the refrigerator into a tank, the bottom of which is about 10 feet above the level of the machinery house in which it is placed, and where it is kept at the required temperature. From the tank the liquid flows by gravitation through about 55 feet of pipe to the rink, and having passed through the tubes imbedded in the ice, returns by gravitation to the refrigerator to be pumped gently up again into the tank. Before, however, the solution enters the main refrigerator it passes through a worm in an auxiliary refrigerator, which is supplied with ice-dust produced by the skaters on the rink, the dust being mixed with salt.

The freezing apparatus is an ether machine, the ether being exhausted from the refrigerator, and forced into the condenser by an air pump driven by a steam engine. About four gallons of ether is the quantity stated by Mr. Gamgee to be in use, while he affirms that it requires but very infrequent renewal, and then only in very small quantities. The refrigerator is a copper box about five feet square, fitted with a series of vertical tubes, and placed in a wooden tank. The glycerine mixture surrounds the copper box and passes through the tubes, the ether of course being inside. The condenser is about the same size as the refrigerator, and is similarly constructed, except that the tubes are placed horizontally, and are double. The condensing water circulates through the inner tubes and outside the outer tubes, whilst the ether passes through the annular space between the two tubes, returning thence to the refrigerator. It will thus be seen that there are two circulating systems maintained, that of the glycerine solution and that of the ether, both of which have worked uninterruptedly since the ice was first formed and the rink opened, which was on the seventh of January last.

THE VALUE OF TIMBER.—An illustration of the value of timber on waste lands is afforded by a sale of wood which took place on the estate of the Earl of Cawdor, in Nairnshire, the other day. In 1820 two hills, about 300 acres in extent, were planted with fir and other trees, and after successive thinnings, the sale of which realized large sums, the remainder of the wood has just been sold off for the sum of £16,000. The sums realized for the wood on this waste land during the 50 years is stated to be equal per acre to the return of this best arable land in the country.

THE California State medical society has held its ninth annual session in this city, the past week, at the rooms of the Young Men's Christian association. The attendance exceeded that of any previous meeting. A large number of new members were received. The association is still in session as we go to press.

MECHANICAL PROGRESS

A Lesson from Japan.

The Philadelphia *Telegraph* draws a lesson from the mechanical work which Japanese carpenters are now doing in the erection of a building on the Centennial grounds. It says: The remarkable deftness of the Japanese house carpenters now at work on the Centennial grounds excites admiration in the hearts of all who witness their operations. Many an American workman who flatters himself that he is skilled in his trade, is forced to acknowledge that those Orientals know a thing or two that is beyond him, and is lost in wonder at the neatness, readiness and thoroughness of their operations. Now, how did these Japanese manage to acquire such a mastery of their trade as they certainly have acquired? Most of the nicest and most delicate work executed by them is measured with the eye, and the rule is not used in innumerable instances where an American mechanic of the first rank would consider it absolutely indispensable for the accomplishment of even an approximately good job. Their fitting, however, is a marvel of exactness in every instance, while their knowledge of certain principles of construction appears to be absolutely exhaustive. We do not believe that the skill shown by these men is due to any superior natural aptness, and we are quite convinced that, no matter what their natural aptness may be, they would never have been anything but bunglers had they not been trained for their business with a thoroughness of which we know nothing on this continent. What the Japanese system for the education of workmen may be like we have no idea, but it is certain that it gives a training for eye and hand which no system that has ever been in vogue hereabouts has ever done. We do not believe, however, that there is any particular merit in the course of instruction given to Japanese mechanics, or that we cannot accomplish equal results with methods of training with which we are familiar. The secret of the whole business is that in Japan a tradesman is compelled to really learn his trade, and is not permitted to only half learn it. He is compelled to place reliance upon the instruments which nature has furnished him—his eyes and his hands—until he has them so educated that he is able to calculate upon them serving him with the best effect under all circumstances. Before our mechanics can hope to do work like that now being done by the Japanese at the Centennial grounds, it will be necessary for them to have eyes that can see straight and hands that will instinctively follow the guidance of the eyes. The importance of securing for the rising generation of workmen such education as will render them skilled laborers in what seems to be the Japanese sense of the term, admits of no question. How it is to be secured to them, except by some thoroughly scientific system of technical education which will commence with the smallest children in the primary schools, we do not know. With some such system—and it is far from impossible to put such a one in operation—excellent results can undoubtedly be achieved, although we are very much afraid that it will be a good many years before we shall see American carpenters doing work like that of the Japanese.

A MAMMOTH FILTER.—James Pearson, of Sacramento, has just completed for Governor Stanford's palatial residence in San Francisco a mammoth filter, four feet in diameter and seven feet in height, made of the best boiler iron, with heads of cast iron, weighing 830 pounds each. The filter is constructed on a patent obtained by the inventor in September, 1873, and practical tests in San Francisco as well as Sacramento have shown that the plan is as perfect as can be desired. The packing is composed of gravel, charcoal and sand, and the arrangement is such that the filter may be attached to the water pipe in the basement of a building and the pressure from the hydrant will force the water up through the filtering material and distribute it through the pipes in every portion of the building. The work of cleansing the filtering material is so easy that it can be performed in a few minutes and every day if desired. The filter made for Governor Stanford will probably be sent down to the bay to-day or to-morrow. It has a capacity of about 10,000 gallons daily.—*Record*.

RECOGNITION OF AMERICAN GENIUS.—*The Manufacturer*, a paper devoted to the interests of manufacturers, published in London, England, says: "The important contributions of American inventors to the every-day wants of the manufacturing or mechanical world have become, to use an Americanism, institutions in England. The fertile genius of our American country is fostered by the exigencies of their climate and altered circumstances, and from them we have had, and are still receiving, some of the most striking discoveries and adaptations of our times. That America can offer most valuable suggestions in several spheres is apparent to the most casual observer." *The Manufacturer* then goes on to mention some of the common inventions that have been put in use in this country, illustrating several of them with wood cuts. Among these are the "quick signal railroad lantern," the "distance measuring wheel," the "lightning screwing and tapping machine," etc., to which it awards the highest meed of praise.

Boiler Explosions.

At the annual meeting of the Manchester steam users' association, held at the Manchester town hall on Tuesday, there were exhibited some large boiler plates, showing the rents that had been formed by hydraulic pressure in a full-sized mill boiler of the "Lancashire" type, constructed entirely for experimental purposes. The plates shown contain the fractures developed. The experiments on this boiler, which have just been brought to a conclusion, have extended over about 18 months. The boiler has been burst 11 times, being substantially repaired after each bursting, the entire outer shell at one time being remade. These experiments have led to interesting and important results, of which the following is an official summary. They have shown the weakening effect that steam does have upon cylindrical boilers, and the importance at high pressures of having manhole mouthpieces, as well as all the fitting blocks, of wrought iron instead of cast. They have also proved that the furnace tubes, when strengthened at the ring seams of rivets with onerous hoops or flanged joints, and the flat ends, when suitably stayed, are stronger than the cylindrical portion of the shell, which tends at the longitudinal seams of rivets. In the recent fatal explosion at Rochester on board the steam tug *Prince of Wales*, the flat end failed before the cylindrical portion of the shell, showing that the boiler was malconstructed. The experimental boiler, which was seven feet in diameter and made of plates 7-16th of an inch in thickness, rent in the outer casing at a cast iron manhole mouthpiece at a pressure of 200 pounds on the inch; at a machine made single-riveted longitudinal seam of rivets at a pressure of 275 pounds on the inch; at a double riveted longitudinal seam of rivets at a pressure of 300 pounds on the inch when hand-made, and at a pressure of 310 pounds on the inch when machine-made. The experiments showed the superior tightness, as well as strength, of double riveted to single riveted seams, and of machine work to hand work. The factor of safety adopted by the association, and which they find efficient, is four to one. It had been calculated that the bursting pressure of the boiler would be 300 pounds, which has been verified by the experiments. Boilers of the dimensions just given are guaranteed by the association at a working pressure of 75 pounds on the square inch. The plates of which the boiler has been made are about to be tested in an accurate machine as regards cohesion and elasticity, so as to check the results obtained by water pressure. When these are completed the entire results will be given to the public. The labors of the association have conclusively shown that steam boiler explosions are not accidental nor mysterious, but that they arise in the great majority of cases from the use of boilers unfit for work.—*Iron*.

PIG IRON PAVEMENT.—Twenty different kinds of paving have been tried in Paris; wood paving has been judged, gutta percha paving is too dear, in bitumen paving there is room for improvement, and now paving by pig iron is to be tried in a few days. A bed of mortar is first laid down, which is covered by a strong layer of asphalt; it is in this layer that the iron cakes, which are about 1.6 inches thick, are set. These cakes, it appears, preserve the homogeneity of the bitumen and prevent its depression, and render the asphalt less slippery for horses. This pavement will cost more, assuredly, than the compressed asphalt, but it is estimated that this mode of paving will save 50 per cent upon the repairing expenses, which are very considerable. The end desired is to avoid, by the adoption of a kind of pavement, the depressions in roads over which a great deal of traffic passes. To attain this it does not suffice to pour bitumen upon a well prepared ground lightly covered with a coat of lime; the resistance of the ground should equal that of an old macedamized bank, and a very thick bed of mortar, which should be very homogeneous, should be laid before the asphalt is laid.

THE SEWING MACHINE IN EUROPE.—At the annual soiree of the employees connected with the extensive works of the Howe sewing machine company, Glasgow, Scotland, recently held, the chairman stated that the British islands alone had taken a third of the machines (61,123), which the company had made in 1875. The little kingdom of Belgium, with her 5,000,000 of industrious people, took twice as many machines in proportion to population as Great Britain; but France, with her 36,000,000 of people, as yet took but half as many as Great Britain, with 33,000,000. Germany, with her 40,000,000, did no better. Italy and Spain, the former with 25,000,000 and the latter with 17,000,000, as yet purchased but a few hundred machines per year. Entire Scandinavia was an unexplored region; while Russia, with her 85,000,000 of active and rapidly progressive people, as yet received but the tenth part of what were now sold in Great Britain.

RAILROAD CROSSINGS.—A bill has lately been passed by the Massachusetts legislature providing that "no highway or townway shall hereafter be laid out across a railroad at a level therewith, nor shall any railroad be laid out and constructed across a highway or townway at a level therewith, without the consent in writing of the board of railroad commissioners, in addition to the authority of the court commissioners, as now required."

SCIENTIFIC PROGRESS.

The Way Bessemer Succeeded.

At the last meeting of the British Iron and Steel Institute, one of the most important matters broached was the success which had been gained in producing Bessemer steel by using iron directly from the top of the blast furnace instead of running it into pigs and then melting anew for the converter, as has been the practice thus far. At this meeting Mr. Bessemer made an address, which describes in a very interesting manner the steps by which he gained success. His experience should prove encouraging to all inventors and investigators. His said:

I am exceedingly gratified to hear the account from three gentlemen to-day of the working of my process with iron direct from the blast furnace. The earliest idea I ever entertained of the process was that we should never remelt the iron, and it was only because I had not access to a blast furnace in my experiments that those experiments were made with pig iron. No doubt I had a good deal of advantage in that fact, because I availed myself of that very point of advantage which the last speaker has dwelt upon, and I was enabled to select the metal. In my earliest experiments I happened by a great chance to buy some excellent Blaenavon iron, and got a result so satisfactory with that particular batch of iron that I was ready to conclude that every kind of iron throughout the kingdom would answer the purpose. The very next kind of iron I tried was that produced by our friends at Dowlais, and I need not tell you that they were making a material not suited to my purpose. I can assure you that turning from one of those metals to the other was the greatest blow that I ever received. My fine-spun theory, that all iron would answer the purpose, was knocked in the head in an instant, and it took me something like two years to recover from that blow. I had to try a variety of irons, and in almost every one of them I was unsuccessful. I then thought it necessary to try whether I could get almost absolutely pure, or comparatively pure, pig iron, and I thought, "If my process succeeds with that there is some hope of it still. If not, I must give the thing up." I then obtained some Swedish iron of a very excellent brand, and the result was satisfactory. This showed me that if we had to deal with pig containing but a small quantity of sulphur and phosphorus, we could get an excellent result. That gave me heart to try again. On looking at the iron ores of England I found that in the Whitehaven district there was an excellent ore called the hematite. I purchased some excellent iron there from the Workington company. My friend Mr. Riley and another chemist in London made several analyses of that iron, and I found to my astonishment that it contained a large quantity of phosphorus, though the analysis of the ore showed no phosphorus. I went to the Workington iron company, and said, "If you have any great secrets do not convey them to me, but if you have none will you please let me see all that you do in the production of your iron, for I have got an iron containing a large quantity of phosphorus, and the ore you are making it from contains none." They placed everything at my disposal, but I was able to trace nothing that would account for the phosphorus. In returning back, however, after two hours' inspection, I saw a large quantity of material in the corner of the yard, and I inquired what it was. The answer was, "That is some flux that we use." I said "What is it?" "Well, you know," said my informant, "we sell a good deal of fine hematite ore to the people in Staffordshire, and they fettle their puddling furnaces with it, and we buy it back again, as it makes an excellent flux." Of course I saw that material had picked up the phosphorus from the Staffordshire ore and brought it back again into the Workington iron. I suggested that they should make me a hundred tons of iron in a blast furnace upon a series of charges which I should dictate. I carefully analyzed three samples of iron ore, three samples of lime, and three samples of coke, and selected the purest of those materials. They made me one hundred tons of iron from these materials, and stamped it with B, which, I believe, was the first Bessemer pig, and that iron gave me so excellent a result that from that period onward we have progressed till we have arrived at what you see to-day. I must say that I am exceedingly gratified to see that it has been found practicable in England to work iron direct from the furnace in my process. I have thought to try myself the tapping of three blast furnaces; and when I advised some of my friends in the neighborhood of Barrow to go into the steel making, they did arrange their works, some two or three years ago, so that pig iron might be tapped into a spherical vessel, with a close top, to hold twenty tons. It was resolved to make three seven-ton tappings, and to have a second vessel so as to keep on continuously, and to keep the heat up and avoid skulking in the transit. In fact, it was intended to work by very similar means to those which these gentlemen appear to have used. I may say how exceedingly gratified I am to find that my earliest ideas have been brought, so far, to a favorable issue.

Artificial Ice Making.

The method of making ice or cooling by means of liquefied carbolic acid gas, and its application to the preservation of meat and fruit during its transportation on shipboard, by cooling the air in the storage-room, has proved a total failure. The machinery needed was too expensive, the great resistance to be overcome in compressing the gas requiring a powerful steam engine and very heavy and strong receivers, capable of withstanding a pressure of some 1,000 pounds or more per square inch, exerted by the liquefied gas. The consumption of coal was found to be enormous, while another difficulty was the failure to diffuse the low temperature (some 100 deg. Fah. below zero) evolved at the spot of expansion, through the whole extent of the room to be cooled. This difficulty was found to be similar to that which would be experienced where a large room had to be moderately heated by the hydro-oxygen blow-pipe, producing an intense heat only at one small spot. The ammonia machine described in some books under the name of the Tellier machine, but properly the invention of Carre, has been moderately successful, and succeeded for a few years in lowering (in New Orleans, for instance) the price of ice to one-half. The natural ice, which in summer can be bought in Boston and New York at the wholesale price of \$3 or \$4 per ton, costs the trading companies in New Orleans about \$16 per ton, (including a loss of 60 per cent. before being delivered to the customers.) The Carre ice machine company had for the last five years set their price at \$15 per ton, claiming that the expense of manufacture (counting interest of capital invested, fuel, labor, and deterioration of machine,) amounted to \$6.50 per ton.

The Tellier ice machines, lately offered for sale, are founded on the use of refrigerating mixtures, as the solution of nitrate of ammonia in water; they have the advantage of low price and simplicity, requiring no great power to drive the simple machinery, only the ice cannot be produced cheaply, as the reconvertion of the dissolved salts into primitive dry condition involves much more labor and expense than the refrigeration itself.

The refrigerating machines based on the principle of cooling by expansion of previously compressed air, first invented by Kirk in England, have attracted some attention during the last four years, and especially Windhausen in Germany has done much to perfect, but unfortunately, at the same time to complicate them.

The art of making ice machines has yet to be learned, as was the art of making locomotives.

A Metric Treaty.

The President has recently sent to the Senate for ratification a treaty, the object of which is to establish an international uniformity and precision in the standard of weights and measures. The treaty is between the United States and the governments of Austria, Argentine Republic, Belgium, Brazil, Denmark, Spain, France, Italy, Peru, Portugal, Russia, Sweden and Norway, Switzerland, Turkey and Venezuela. It contains an agreement between all the parties to maintain in Paris, at the common expense, a permanent bureau of weights and measures, to be under the control of an international committee. The bureau is to be charged with the following duties:

1. All comparisons and verifications of the new prototype and of the meter and kilogramme.
2. The custody of the international prototypes.
3. The periodical comparison of the international standard with the international prototypes and of test copies, as well as comparison of the standard thermometers.
4. The comparison of the prototypes with the fundamental standards of non-metric weights and measures used in different countries for scientific purposes.
5. The standardizing and comparison of geodesic measuring bars.
6. The comparison of standards and scales of precision, the verification of which may be requested by governments, scientific societies, or even by constructors or men of science.

NEW SIMPLE SAFETY LAMP.—For some time the police and night watchmen of Paris have been provided with a very simple safety lamp, which they are ordered to use in all shops and warehouses where inflammable materials are kept. A piece of phosphorus about the size of a pea is introduced into a strong glass bottle, and on this is poured warm olive oil, filling about one-third of the bottle, when it is closed with a tight fitting cork. When it is desired to use this lamp, the stopper is removed a moment, so as to give access to the air, when at once the empty space over the oil becomes luminous, and diffuses a light sufficient to find the way in the dark and effect things are all right. When the intensity of the light diminishes, it is sufficient to lift the stopper a single moment, when by the admission of atmospheric air the light is at once restored. Such a lamp can be used nightly for about six months without undergoing any perceptible decrease in efficiency.

PRICES OF METALS.—One pound of iodine will purchase 132,354 pounds of iron, about eight and a half of gold, 22½ of platinum, 135 of silver, 1,018 of nickel, 1,654 of mercury, 6,617 of antimony, 7,780 of tin, 10,180 of copper, 17,650 of zinc, and 24,070 of lead.—*Les Mondes*.

Mining Share Market.

The past few days have witnessed the most sudden and startling revolutions in the stock market. The fluctuations have been more rapid and, in many cases, more disastrous than any changes which have occurred since the great Virginia fire. The general market has been on the down grade for some three weeks or so; and, although the usual summer decline was anticipated, no such panic as has fallen upon California street was looked for. The causes of this marked fall in prices are evident enough, though this would bring small consolation to the suffering public. In the first place nearly every mine and group of mines had had its or their regular winter "deal," the inevitable result of which is to load up the small operators with depreciated stock to their fullest capacity. There had been no astonishing developments made, no new ore bodies of consequence authentically announced, and consequently there was no prop to support public enthusiasm and keep up the excitement. Then, the time is drawing close at hand when the annual drain of coin to the interior begins, a call made by the farmers upon the city for means to meet harvesting expenses, settle accounts, etc., which causes a loss of capital in town not to be relieved until the fall months, when the crop returns from abroad begin to flow in. Besides this, many prominent operators have closed out their accounts, preparatory to making an Eastern or European trip, thus taking a good deal of money out of the market, much of which has gone into real estate for permanent investment. Finally, and to crown all, a feud between the bonanza house of Flood & O'Brien and the clique represented by Jas. R. Keene was reported, and worked up into a highly embellished episode in the sensational press. Mr. Keene is said to doubt the permanency of the Consolidated Virginia ore body, and predicts an early suspension of dividends. Acting upon this information, the whole force of operators, big and little, have simultaneously thrown their securities upon an already overloaded market, thus uncovering quantities of margin stock and precipitating a grand crash, which has been general and sweeping, more or less affecting every stock upon the list. Naturally the weight of the shock falls principally upon the Comstock, and the first to recover will be probably the stocks of the E. Y. and Eureka districts, which have had no "deal" as yet. By reference to our table of comparative quotations the amount of shrinkage in each direction will be perceived.

California Stock Board.

between the bonanza house of Flood & O'Brien and the clique represented by Jas. R. Keene was reported, and worked up into a highly embellished ebape in the sensational press. Mr. Keene is said to doubt the permanency of the Consolidated Virginia ore body, and predicts an early suspension of dividends. Acting upon this information, the whole force of operators, big and little, have simultaneously thrown their securities upon an already overloaded market, thus uncovering quantities of margin stock and precipitating a grand crash, which has been general and sweeping, more or less affecting every stock upon the list. Naturally the weight of the shock falls principally upon the Comstocks, and the first to recover will be probably the stocks of the E y and Eureka districts, which have had no "deal" so yet. By reference to our table of comparative quotations the amount of shrinkage in each direction will be perceived.

This (Thursday) afternoon there was no session of the San Francisco stock exchange on account of the ceremony of laying the corner stone of the brokers' new building on Pine street. Speeches were made and a collation served afterwards in the board room. On the street after the morning board prices were worse than ever, everything falling off still worse than for the past two days, and as bad, if not worse, than at the time of the bank failure.

CLOSE SHAVE.—There was a close shave from a dreadful accident at the Combination shaft Sunday night. Four men had put in as many blasts, and after lighting the fuses rang the signal for the bucket to be drawn up. Before the fourth man could get in, the bucket shot up, leaving the miner at the bottom amidst the fizzing fuses. The men in the bucket seized the rope and gave the signal to descend. When they reached their comrade he had succeeded in putting out two of the fuses. They dragged him in and once more began to ascend. When the blasts went off the miners were high enough to escape harm.

THE SANTA RITA PLACERS.—News from the Arizona mines continues to improve. On the 8th inst. sixty ounces of gold dust was brought from the Santa Rita placers, valued at over \$1,000. Among this dust was one nugget weighing three ounces, perfectly pure and free from foreign substances. There is naturally more or less uneasiness among the miners on account of the late Indian outbreak, but work is progressing with usual activity. The number of men at the Santa Rita placers is now about 150.

MIXED.—The affairs of the Mechanics' mine, in Calaveras county, are rather mixed. The majority of the shareholders are represented as anxious to resume work upon the mine, while one of the shareholders is opposed to it and holds the books, papers, etc., of the company in his possession. If the majority want to work we do not exactly see how the single shareholder prevents them, simply by holding the books, etc.

THE Consolidated Virginia, California, Ophir and Belcher mines have each 200 sacks of good average ore ready for shipment to the Centennial exhibition at Philadelphia. These sacks of ore will weigh from 100 to 110 pounds each, and the ore is intended for crushing in the quartz mill now being exhibited at the exhibition grounds by the commissioners of Nevada.

the east cross-cut is steadily advancing, with no new development of interest, and both side drifts north and south from it are showing well, in favorable looking quartz, which promise better developments. The main incline is now down to the 1200-ft level.

GOLD & ORE.—The excavation work for the new and powerful pumping machinery is advancing well, and the north drift at the 1700-ft level will be ready in a few days for the resumption of ore development or prospecting at that point. The shaft is in complete repair, ready for active operations.

KOSKUTZ.—Drifting both north and south at the 500-ft level progresses well, following the vein and the ledge. No cross-cutting as yet. A raise is being made for the south drift of the 320-ft to meet the winze being sunk from the level above, for air circulation purposes.

OVERMAN.—Bottom of shaft still in very hard rock, with something of an increase in the already strong flow of water coming in. Cross-cut east at the 1100-ft level still pushing ahead well. Nothing new to report here or elsewhere in the mine.

SAVAGE.—The tank stanks and hob pits in the shaft, as low down as the 1800-ft level, are completed, or nearly so, and the excavations at the surface for the new and very powerful machinery contracted for are being pushed ahead industriously.

BEST & BELCHER.—Good work is being done completing the drift connecting with the Gould & Curry at the 1700-ft level, and in about a week prospecting the ore vein at this level will be resumed under the most favorable auspices.

NORTH CO. VIRGINIA.—Shaft down 846 feet; bottom in very favorable looking vein matter of a decidedly mineral bearing nature. Some increase of water, but not interfering with the regular good progress of the work.

WARR.—The new shaft is started in a very eligible and advantageous location, and is getting along finely. The grading and other surface work, as well as building preparations, are getting along lively.

DAYTON.—The regular development work at the various levels in this mine goes steadily ahead as usual, and the 750-ft level of the shaft is being opened for, a new working level at that point.

PROSPECT.—Main shaft 198 feet deep, and sinking lively, under a contract let to sink it to the depth of 500 feet. The Ingersoll rock drill is to be employed in this work. The requisite arrangements will arrive tomorrow, and put into operation forthwith. The diamond drill, which was being used for prospecting ahead from the surface, has been discontinued. It passed entirely through the ledge, which it showed to be over 100 feet wide, and giving assays all the way through it which averaged not far from \$100 to the ton. The Prospect company have a good thing when they get down to it with their shaft.

ONTARIO GOLD HILL.—The main shaft is now being retimbered at points where the swelling of the ground has rendered it necessary, and when this work is completed, sinking deeper will be resumed in order to open another level and get at the lower portion of the fine ore body developed in the southern portion of the lower level.

GLASGOW.—This mine is being worked through the combination shaft sunk by the Amazon and Glasgow mining companies. The company have now 17 1/2 acres of ground, titled United States patent, shaft sunk 317 feet, and cross-drifts run the vein and the ledge. The company are now opening up the mine on the 300-ft level. The vein on this level shows some good sulphuret ore, with fine enclosures for finding more as the drift penetrates the vein.

SERRA NEVADA.—Sinking the main shaft is making the usual good progress, the bottom in good working ground. The north drift on the 1500-ft level is opening up fine beds of quartz, and the ledge appears to be much more compact and of a more favorable character at that point than it has shown for some time past on the levels above. On both the 1550 and 1000-ft levels work is going ahead without any changes of interest whatever to report.

LADY WASHINGTON.—Bottom of shaft in very favorable ledge matter, showing considerable improvement, streaks and bunches of fine looking quartz coming in. The material is soft and easily worked, allowing of fast sinking. The pump-bob station at the 600-ft level is completed, and the hole will be sent down and put into working trim forthwith. The new pump and machinery working splendidly.

FLORIDA.—The new machinery is being started up in good shape, and water pumped out of the shaft. Work is resumed, cleaning out and fixing up the drift at the 300-ft level. Sinking will be resumed at an early period for a new level, the developments already made at the 300-ft level being sufficient to show that there is something below well worth going to.

KAISERBERG.—Sinking the main shaft goes ahead actively as usual to open the 300-ft level. Water does not interfere, consequently excellent progress is being made. No large bodies of ore have been met with in the drifts of the lower level thus far, but the showing is exceedingly good for something better before long.

TWIN PEAKS.—Shaft down 80 feet and the splendid ore vein developed at the bottom, mentioned by us a few days ago, is showing, and shows more promising than ever. It is a valuable development and will be followed very energetically. The ore assays well, is of a white granulated texture, and bide fair to lead into a nice little bonanza.

UTAH.—The station is about completed at the 750-ft level, ready to start drifts to cross-cut and prospect the ore vein at that point. The flow of water at the bottom of the shaft remains much the same, giving some trouble to the men engaged in sinking, but is easily handled by the pumps.

SILVER HILL.—Putting the heavy pump in the main incline, with which to drain the flow of water recently struck, is going ahead with all possible energy. There is no particular change to note of the east cross-cut on the third station level, or the cross-cut from the bottom of the new winze.

MONTECAL.—Sinking the shaft is making good progress, the bottom in porphyry interspersed with occasional streaks and stringers of quartz that give low assays of gold and silver, and that look as if it would not now take long to reach the ledge. It is now down 138 feet.

COSMOPOLITAN.—Work is resumed in the face of the main tunnel or adit, following the vein farther to the northward. The upraise in the ore body at this point is up 75 feet and showing well in good mill ore.

LARRY BRADY.—The removal of the old shaft and the pumping machinery, to make room for the deep excavations for the foundations of the new, is going ahead with great vigor. Otherwise nothing new.

CALIFORNIA.—Daily yield 300 tons, all of which is now being crushed by the new mill of the company. This ore is very rich, and gives a splendid showing of bonanza into the company's treasury. Next month another mill will be set to work on ore from this mine, as the widening out of the ore breasts gives additional facilities for extraction. The sinking of the winze below the level of cross-cut No. 6, on the 1550-ft level, is going steadily ahead. With the exception of the extraction of ore, sinking this winze is about all the work that is being done in the mine at present. This winze will be sinking to the depth of 100 feet or more for the double purpose of prospecting the ore vein and affording an air winze whenever the development of the mine below the 1550-ft level is commenced. The California is very likely to take the lead before many months, as the chief producing and dividend paying mine on the Coast.

WARR.—Daily yield, 150 tons of ore. The various breasts are being worked out fully and showing improvement at some points in both quality and quantity. The billion yield for the month will be about \$300,000. At the 1600-ft level the ore shows considerable improvement. The drift south at the 1100-ft level is in better material and cross-cutting will be commenced shortly. The east shaft, from the 1450 to the

1700-ft level, is now fully cleaned out and reopened, and work is resumed at the 1700-ft level once more. The fourth compartment of the main shaft is now completed to 1450-ft level, and the Ophir mine to day is in better working shape than she has been for many months at least.

UNION CONSOLIDATED.—At the 1300-ft level the whole face of the north drift is now in very fine quartz, showing considerable improvement over last week, and giving promise of something better shortly. It continues widening as the drift progresses. The winze below the 1300-ft level is now completed to the 1450-ft level, and a drift started from it to connect with the Mexican. It is in very promising quartz and other vein matter.

MEXICAN.—The northeast drift at the 1450-ft level continues advancing along the wall of the ore vein, occasionally cutting into the side of it, and showing streaks of good ore as it does so. Cross-cutting will be commenced about the middle of next week, when very interesting results may be looked for in the drift.

IMPERIAL.—Face of north drift at the 2000-ft level, running toward the Alpha, still in rich ore. Owing to the drift following the trend of the ledge to the eastward, it is not within 60 feet of the Alpha line, and actual survey would probably show a still greater distance. The drift of the Alpha company, in the Imperial ground, is not into the ore vein as yet, although the indications are favorable.

BULLION.—Main incline progressing downward at the usual good rate, and sinking the north winze from the 1400 to connect with the upraise from the 1700-ft level also progresses well. The face of the northeast drift, at the 2000-ft level, continues in hard black dyke. Some more water is coming in, but not enough to interfere with the work.

BELORE.—Daily yield, 500 tons of ore. The various ore stops and breasts are holding out well, and all the mile are kept running steadily. The powerful new pumping machinery is being placed in working position as fast as is practicable with such heavy work.

WEST BELORE.—West drift now in 140 feet, from which point now drifting northwest to strike the incline. The drift is now in 45 feet in good working ground and with splendid indications. Expect to strike this ledge next week and will commence milling ore.

BALTO CONSOLIDATED.—The hoisting works building is being put up as fast as possible, and the new machinery will be in working position shortly. Mine looking well, and only waiting for the assistance of the new machinery to make a fine showing.

BOOKER.—A full force of men at work grading for the new hoisting works, and foundations for the new machinery, which is all on the ground ready to be placed in working position as soon as possible. All the lumber is also on hand.

AMAZON.—Excellent progress is being made in sinking the joint shaft deeper. At the 300-ft level 24 feet have been added to the drift into the Amazon ground, and fine white sulphuret ore shows in the face.

GRANT.—Prospecting work at the 1800-ft level goes ahead as usual, with no particular change to report. At the 1700-ft level the face of the drift continues in low grade ore, showing a little improvement.

SUPERIOR.—Shaft 80 feet deep to-day, and sinking in porphyry and quartz. Rock hard in streaks, but working well. No water. Drifting suspended at present, and all work concentrated on sinking the shaft.

SUCOCK.—The heavy flow of water encountered in the shaft has subsided a little, but still impedes sinking considerably. Prospecting work at the 550-ft level goes forward as usual. Nothing new.

WOONVILLE.—Under the new management work is well started up and driving ahead lively. Shaft and drift arrangements are being straightened out, and ore production will be better.

TROIAN.—The new machinery will very shortly be completed, ready to start into working operation, when the ore resources of the mine will be sought into and made available.

RED AND WHITE CROSS.—The timbering of the shaft being sufficiently advanced and the galleys or hoisting frame up, sinking is resumed in the main shaft under the most favorable auspices.

HALE & NORTON.—Lively work is being done with the deep excavations for the heavy new machinery foundations, and everything is being pushed forward with characteristic energy.

ROCK ISLAND.—Good work is being done in the drifts at both the 650 and 850-ft levels. Both drifts are advancing well, with good prospects. No new features to report.

NACARA.—The incline shaft is down 283 feet, the bottom in soft ledge matter of a very encouraging character. The sinking is being pressed ahead with great energy.

MORNING STAR.—Sinking shaft at the usual good rate of progress, with no new features to report.

CON. VIRGINIA.—Daily yield, 600 tons. Notwithstanding the great quantities of ore taken from the producing levels of this mine, the diminution of quantity in the great bonanza mass is not so great as might naturally be expected, and depends upon thousands of tons are still in sight, with plenty more to be got when required. At the 1500-ft level the east drift to connect with the C. & C. shaft is steadily advancing in good running ground, and the diamond drill is kept well in advance, in order to guard against any possible unexpected cutting into the heavy body of water known to be in that direction, and being now drained by the C. & C. shaft. This flow of water has been very heavy, but easily managed by the powerful pumps, and it seems now to be on the decrease, the quantity being now 40 inches, miners' measurement, against 43 inches last week. It has been as high as 53 inches.

JUSTICE.—The usual amount of ore comes from the 600-ft level, sufficient to keep the mill running steadily. At the 1000-ft level the north and south drifts are steadily advancing, and cross-cutting will probably soon be commenced at that level. At the 800-ft level the cleaning out and repairing of the south drift is completed and work is resumed at the face in order to carry it through to a connection with the south winze, which has been completed to the 800-ft level.

GLOBE CONSOLIDATED.—The machinery and all other working arrangements are being put in first-rate working trim for the season. The mine will soon be at full work again.

CALIFORNIA.—Water shows some increase, but does not interfere with the good progress being made sinking the shaft. Rock hard at the bottom but blasts well.

PHIL. SHELDON.—The machinery is in place, and the new hoisting works building completed. Everything will be in readiness to start up in a very few days.

NEVADA.—Face of the main drift north all in quartz, which is low grade ore, and showing constant improvement in assays with further advancement.

SOUTH COSMOPOLITAN.—Face of cross-cut still in low grade ore and porphyry. Water decreasing. Total length of cross-cut 335 feet this morning.

SENATOR.—Working day and night preparing to resume sinking the main shaft. Water much reduced and decreasing.

VIVIAN.—Old level giving a very fair yield of pay ore, and south drift driving ahead well in promising ground.

MINT.—Sinking will be resumed in the shaft as soon as the water is got rid of. The new cable works finely.

ROUGH & READY.—Good progress being made sinking shaft, rock working well and water not interfering.

DARDANELLES.—North drift showing well in face. No new developments to report.

PROCTOR.—North drift pushing ahead as usual. No new features to report.

ROCK ISLAND.—Face of drift showing well in fine stringers of quartz.

BOSTON.—Material in bottom of shaft looking and promising finely.

NORTH CARSON.—Face of drift still in hard rock.

THE ENGINEER.

A New Hydraulic Canal Lift.

At a recent meeting of the British Institution of Civil Engineers a paper was read by Mr. Sidsingham Duns, C. E., descriptive of "The Hydraulic Canal Lift at Anderton, on the river Weaver." The object of this lift was to transfer floating barges between the Trent and Mersey canal and the river Weaver, and thus to afford an easy and expeditious means of communication between them, without the expense and delay hitherto incurred in transshipping goods. The idea of lifting the laden barges by hydraulic power originated with Mr. Edward Leader Williams, Jr., M. Inst., C. E., at that time engineer to the trustees of the Weaver navigation. He consulted Mr. Edwin Clark, M. Inst., C. E., on the subject, and after various designs had been considered, the arrangement of the details and the superintendence of the construction were entrusted to the author. This canal and river were closed together at Anderton, but the level of the water in the canal was 50 feet four inches above that in the river. The water in the canal was conducted by a wrought iron aqueduct, 162 feet six inches long, across an arm of the river to the end of the lift. This aqueduct was in three spans, of 30 feet, 75 feet, and 57 feet six inches. It was 34 feet four inches wide, and a central web divided it into two channels, each 17 feet two inches wide. This central web and the sides of the aqueduct were eight feet six inches deep, and formed continuous girders, which carried the aqueduct and the water, five feet three inches deep, contained within it. This total weight of the aqueduct and the water was 1,050 tons, or about six and a half tons per lineal foot. Excepting at the end, where it rested on the masonry of a basin leading into the canal, the aqueduct was carried on cast iron columns. The lift was double; each half consisted of a wrought iron trough 75 feet long and 15 feet six inches wide, capable of containing barges floating in water five feet deep. The sides of the trough were nine feet six inches deep at the center, and seven feet six inches deep at the ends, and formed girders to carry this weight of the trough, water, and barges, which amounted to 240 tons. This weight was transmitted from the sides to the head of a central ram, three feet in diameter, by cantilevers which radiated from the ram to the sides of the trough. The trough was thus supported and moved up and down by one central vertical ram, which worked in a press sunk within a cast iron cylinder below the bed of the river. This pressure on the ram amounted to about four and three-quarter cwt. per square inch. The trough had a lifting gate at each end, for the ingress and egress of barges, and there were corresponding gates in the aqueduct, so that boats could pass between the aqueduct and the trough, according as they were to be lowered or had been lifted. The press under one trough was connected by a pipe, five inches in diameter, with that under the other trough, and thus water contained in one could pass freely into the other, by an equilibrium valve in this pipe. There was also a small steam engine continually pumping water into an accumulator, to assist in the working of this lift. Piping four inches in diameter passed from the accumulator to each of the presses, and the accumulator could be opened to either of the presses as required. All the valves for working this apparatus were under the control of one man in a valve house on the top of the aqueduct. In working this lift, when one trough containing barge and water five feet deep was at the top of the lift, the other containing barge and water four feet six inches deep was in the river below. As the upper trough was heavier than the lower one, it followed that as soon as the valve on the five-inch pipe was opened, the upper trough descended and lifted the lighter one out of the river, until, by becoming in its turn immersed in the river below, it lost part of its gravitation, and forced the lighter trough to within four feet six inches of the top of the lift. The valve on this five-inch pipe was now closed, and this remaining water in the press under the descending trough was allowed to run to waste into the aqueduct. The trough consequently descended into the river, and the barges it contained had been lowered from this canal to the river. While this was going on the accumulator was opened to the press of the ascending trough, and this trough and barges were raised to within six inches of the top of the lift. The barges were lifted the remaining six inches by letting this depth of water into the trough from the aqueduct. Thus a depth of six inches of water over the area of the trough, taken from the upper level, was sufficient to lower one trough from the canal to the river, and, at the same time, with a little assistance from the accumulator, to lift the other from the river to the canal. Automatic siphons insured a depth of four feet six inches of water in an ascending trough. The edges of the gates were kept water tight with india rubber, and this same material was used for making a joint between the troughs and the end of the aqueduct. The time required to lower one trough and to lift the other was three minutes, and the whole operation of transferring barges from the canal to the river, and others at the same time from the river to the canal, was eight minutes. In a chain of locks at Ruacorn having the same fall, a boat could only pass one way in one hour and a half. A very small staff was required to work the apparatus, and the total weekly expenses

did not exceed £10. In addition to the time saved by this lift, compared with a flight of locks having the same fall, it was stated that, when the traffic was equal in such direction, only six inches of water over the area of the trough were used, instead of 50 feet required by the locks. The lift was publicly opened by the trustees in July, 1875, and had given great satisfaction.

Maritime Engineering.

A new plan of dredging river and harbor bottoms has been proposed, which commends itself to the notice of engineers. In removing soft mud and silt from sea and river bottoms a notably interesting device has recently been exhibited. The plan is to use a steam tug or barge of large size and fitted with powerful engines, both for its propulsion and the movement of its dredging machinery. Just abaft the center of the boat, four holes are made in the bottom, and to these are fitted iron pipes, having flexible joints, so as to hang freely below the keel. These are joined together by a framework, and, by means of a crane at the stern they may be raised or lowered at will. Each pipe terminates in a bent shoe, having openings at its sides. When at work they rest lightly in the mud at the bottom, and, being flexible, readily adjust themselves to the changing depth caused by the waves, the tides or the shoaling of the water. Through these pipes is sucked up, by the natural pressure caused by the displacement of the boat, the loose mud and sand to be removed. It enters the hold of the boat under considerable pressure, and, by the aid of steam pumps, is thrown up through pipes to the deck, and thence onto board into barges alongside. Fitted with such tubes, each 10 inches in diameter, such a boat, it is estimated, will lift and discharge 32,000 yards of silt in 10 hours. With clean sand, an increase of 20 per cent. over this is estimated. This plan also presents another interesting feature in a machine for tearing up and loosening hard packed silt, and preparing it for the suction tubes. This consists of an iron fork or harrow, revolving on its own axis, and supported on a framework, lowered by chains from the bow. By this means it is kept at any required angle, and, by means of a chain belt, it is caused to revolve, and thus tear and rip up the bottom just in advance of the pipes. When at work the boat is designed to be advanced by means of a line of secured moorings and leaving a path on the bottom of varying depth, according to the character of the material. Each pipe sucks up a wide area about its mouth, and, in case of choking or stoppage, may be instantly cleared by raising the pipes from the bottom and allowing the clear water to sweep through. When not in use the harrow and pipes may be raised to the keel, and the boat then moved to another spot. This new dredging machine has been made the subject of exhaustive experiment, with satisfactory results.

BARON DE LESSEPS.—The man who made an international fame in carrying the project of the Suez canal to a successful completion, Baron de Lesseps, is pleasantly gossiped about by a correspondent as follows: Though 70 years old, he is still a young man, and contemplates grand designs which it is to be hoped he will live to carry out. With black eyebrows and mustache, but white beard, he is a most noticeable man, and those who do not know him take him to be a sergeant in the gards. He brings his children up in the most Spartan—or shall I say Egyptian?—way. They go about barefooted, and, although Madame only half likes this, he is able to boast that their young ones, of whom they have a small regiment, are never ill. His house is full of gifts from great persons. There is a gold cup given by the Empress worth \$40,000. All the sovereigns present or represented at the opening of the canal sent him ribbons, making him one of the most decorated men in Europe. He now desires to make a railway through the Euphrates valley. He says: "I do not care for riches, and I have no wants; all I wish is that my children may grow up and prosper. I satisfy myself with the hope that they will get on in life, proud of their father, and happy to continue his work, which is that of humanity and civilization."

FRENCH ENGINEERING PROJECTS IN AFRICA.—The vast engineering project of filling a depression in the Sahara desert by allowing the entrance of water from the Mediterranean, is still discussed in the French scientific journals. Mr. Honyvet remarks, in a communication to the French Academy, that it will not be difficult to establish this sea—the problem is how to keep it. Supposing the sea be established by means of a canal there must be an enormous quantity of water lost by evaporation. The water evaporated being replaced by a supply coming through the canal, the whole body will soon reach the maximum of saturation. This evaporation still continuing, a deposit of salt will be formed, which in time will fill up the whole space of the interior sea, the ultimate result being simply the accumulation of an immense deposit of salt. The advocates of the project are very strongly of this opinion, however—based upon this most painstaking and protracted investigation by eminent experts—that the presence of this water, and its evaporation, will produce copious rains, which will, in a great measure, return into the sea, and not only accomplish the object referred to, but also convert what is now a sterile waste into a fertile country.

GOOD HEALTH.

Sleep.

At the London Institution Professor Ferrier, of King's college, delivered a lecture on this subject before a large and deeply interested audience. Dr. Ferrier began by remarking that no living being is capable of continuous, uninterrupted activity. All work implies waste, and the possibility of continuous life and activity necessitates as a postulate the constant repair of the waste of action. During active work the process of waste is in excess of the process of repair; hence, if action is kept up a period comes when the stores of energy are expended. In action, rest or repose follows, during which the waste is repaired or made good, and the duration of this period of inaction will depend on the rate at which the process of repair progresses. During the period of inaction, or sleep of the muscle, the wasted tissues were again restored, the period of rest depending on the degree of exhaustion.

What was true of the muscle was true, *mutatis mutandis*, of the organs of digestion. Some organs seemed to be in a state of constant activity, and therefore might be thought to be exceptions to the general law laid down. This, however, was not so; for in reality these organs, the heart and respiratory organs, were not in a state of constant, but of rhythmical activity, a period of action being followed by a pause or rest. The only difference between the heart and the voluntary muscles was that the periods of action and inaction of the heart were short and followed each other in quick succession.

The brain, the organ of conscious activity, was kept in constant action during the day for many consecutive hours, and therefore it was necessary that there should be a correspondingly prolonged period of relaxation from action, and repair of the brain waste condition by all thought, solution, etc. The rest of the brain was sleep *par excellence*, but, in addition, sleep was the period during which the repair of the excess of waste over nutrition in the body generally occurred, in so far as it had not been made good during the day. This was proved experimentally by the researches of Pettenkofer and Voit, who showed that, in reality, more oxygen in the form of carbonic acid, etc., was given off during the day than was taken in, and it was during the sleep that the excess of oxygen was stored up as a reserve fund against the possible needs of the following day. The relation of the duration of sleep to the period of action and its modifying circumstances were also considered, and a parallel drawn between the average duration of sleep and rest of the heart. The physiological condition of active exertion on the part of any organ is an active circulation through it. The local increase of the circulation or local hyperæmia was brought about through reflex dilations of the blood vessels, effected by the organs or tissues themselves. Muscles in a state of action drew a much larger supply of blood than when quiescent; so, also, the stomach digestion. The same was observed in the brain during active thought. This had been demonstrated by direct experiment, and it was also shown, indirectly, by the fact that when a large amount of blood was drafted off to any one particular organ, there was an impoverishment of the circulation elsewhere. Hence deep thought, necessitating a large supply of blood on the brain, was unfavorable for digestion. Also, in deep thought, the circulation became feeble in the extremities, hence cold feet, etc.

In sleep the brain is anæmic. This has been shown by Durham, Hammond, etc., by way of direct experiment. This is proved also indirectly by the greater quantity of blood which circulates in the skin and extremities during sleep, because there is a greater radiation of heat from the skin. Whatever tends to abstract blood from the brain favors sleep. Hence digestion tends to cause sleep, as do hot drinks, etc., by drawing the blood supply from the brain to the stomach. Conversely, whatever tends to keep up the activity of the brain cells and the circulation, tends to prevent sleep. This, therefore, is the effect of any stimulus applied to the senses, sights, sounds, thought, anxiety, etc. The opposite favors sleep. Hence night is the period of sleep, because sources of disturbance or stimulation of the organs of sense is diminished or altogether lulled.

HOW TO MAKE RAW MEAT PALATABLE TO INVALIDS.—The following recipe for this purpose has been given by Iyon:

Raw meat (from the loin) 250 grammes (8.7 oz.)
Shelled sweet almonds, 75 grammes (2.6 oz.)
Shelled bitter almonds, 5 grammes (.17 oz.)
White sugar, 80 grammes (2.8 oz.)

These substances are to be beaten together in a marble mortar to a uniform pulp, and the fibers separated by a strainer. The pulp, which has a rosy hue and a very agreeable taste, does not at all remind one of meat, and may be kept fresh for a considerable time, even in summer, in a dry, cool place. Yolk of egg may be added to it. From this pulp, or directly from the above substances, an emulsion may be prepared which will be rendered still more nutritious by the adding of milk. Lailler prefers the following preparation:

Dried raw meat, 100 grammes (3.5 oz.)
Sugar, 40 grammes (1.4 oz.)
Wine, 20 grammes (.7 oz.)
Tincture of cinnamon, 3 grammes (.1 oz.)

It is a kind of electuary, very agreeable to the palate.—*Industrie Blatter*.

UNDER AND OUTER GARMENTS.—Woolen stuffs are the best materials for clothing in every climate. In warm countries at noon-day, when the vertical rays of the sun strike down in their greatest intensity, the want is to keep the heat out, and a bad conductor is as useful there for this purpose as it is in the Russian snows to keep the heat in. The old lady with her wraps of shawl and fur-lined hood, wending her way to her whist party in St. Petersburg, on a December night, has a strange counterpart in the gallant young officer mounted on his Arab steed, with his head enveloped in turbaned shawls six inches deep, traversing the plains of Hindostan under a burning sun in the month of June; yet both are practical philosophers, despite the blow-blot and blow-cold objection. Hence, also, the flannel costume of the stokers in ocean steamers, who are exposed to intense radiating heat, and they are in this way enabled to bear and resist it; whilst we prevent or check the melting of ice by wrapping it in flannel or straw. White is the best color for protection against both heat and cold; and prominence should be given to this inculcation of the hygiene of dress.

BEST ANIMAL FOOD.—In a recent work on different foods, physiologically considered, the author argues that the best animal food is the flesh of the sheep, and the best vegetable food that of or from wheat. The variety and proportion of the ingredients in a pound of wheaten flour furnish a fair evidence of the value of this grain as a general aliment: Water, 2 ounces, 106 grains; gluten, 2 ounces, 21 grains; albumen, 126 grains; fat, 84 grains; fiber, 119 grains; ashes (salts), 112 grains. Ingredients such as these, in the proportions peculiar to wheat, are admirably adapted to maintain the human body in health and vigor.

LIME JUICE AND PEPERINE.—Dr. Farr, of London, has started the idea of administering pepsine in cases of dyspepsia, in conjunction with lime juice. He believes that the anti-scurbutic value of the latter is due to its power of dissolving certain portions of food; and having regard to the fact that the gastric fluid invariably contains acid of one kind or another, he concludes, not unreasonably, that the acid may perhaps claim some credit in promoting the digestive process.

USEFUL INFORMATION.

How to Lay Shingles.

Not one-half the persons who lay shingles when making a roof on a building have any correct ideas in regard to making a roof that will be absolutely "rain-tight" during a driving storm of rain. We have frequently seen men shingling, who, when they would meet with a worthless shingle, say once in laying two or three courses, would lay this poor shingle among the good ones, saying: "It is only one poor shingle—one shingle cannot make a poor roof." But one poor shingle will make a leaky one. If first rate shingles are employed and one poor one is worked in among every 100, that roof might about as well have been without any shingles. If any poor shingles are to be used let them all be laid together near the upper part of the roof. The best of shingles will not make a tight roof if they are not properly laid, while the same shingles would make an excellent roof if laid as shingles should be laid.

The correct rule for laying shingles of any length, in order to form a roof "leak-tight," is to lay the courses less than one-third the length of the shortest shingles. For example, when shingles are 18 inches long many of them will not be more than 17 inches in length. Therefore, five inches is all that the courses will bear to be laid to the weather with surety of forming a good roof. The shingles must be three thicknesses over the entire roof. If they are not three thicknesses—if now and then a shingle lacks a quarter or half an inch of being long enough to make three thicknesses—there will, in all probability, be a leaky place in the roof at such points. Moreover, when the lower courses lack half an inch, or even a fourth of an inch, of extending up far enough to receive the rain from the outermost course, in case the middle course were removed, it would be just as well to lay them seven or eight inches to the weather as to lay them only five, or five and a half inches. Many shingles are only 16 inches long, and many that are sold for 16 inches long will hardly measure 15 inches. In this case, if the roof be rather flat—say about one-quarter pitch—four and a half inches is as far as they should be laid to the weather. In case a roof were quite steep it might answer to lay the courses four and three-quarter inches to the weather.

When buildings are erected by the job, proprietors should give their personal attention to his subject, and see that jobbers do not lay the courses a half inch too far to the weather.

There is another important consideration which is too frequently overlooked in shingling, which is "breaking joints." Careless workmen will often break joints within half an inch of each other. When the joints of the different courses come so close together the roof will most certainly leak. Why should it not? There is nothing to prevent it during a heavy rain. Unless a roof is steeper than a quarter pitch much care should be taken to break joints not less than one and a quarter inches. Let all workmen and helpers be taught the vast importance of rejecting every poor shingle, except when the upper courses are being laid.

Cleaning Mercury.

Mercury is much used in various physical and chemical experiments, and frequently becomes so dirty and impure as to render it unsuitable for many purposes.

The impurities may be divided into three classes; first, mixture with metals, especially lead, zinc and tin; second, common dust and dirt; and third, water or other liquids.

Redistillation is almost the only way to remove the metals, and even this is not perfectly effectual in the case of zinc. The mercury used for amalgamating battery plates should, therefore, be kept separate from the rest, and used for this purpose only.

If but little of the metal is present, it may be removed by agitation with dilute nitric acid. Instead of nitric acid, a solution of nitrate of mercury may be used.

A great variety of devices are used to remove the mechanical impurities of mercury. It may be poured into a bag of chamois leather, which is squeezed until the mercury comes through in fine globules; or it may be poured into a funnel provided with a filter paper, in which a needle hole has been pierced.

Mercury may be washed directly with water, by shaking them together in a bottle, or filling a jar with mercury and allowing water to bubble through it. To ascertain if mercury is pure, it may be poured into a porcelain evaporating dish. If lead is present, it will tarnish the sides. A thin film will also, after a time, form on its surface, due to oxidation; zinc and tin produce a similar effect. The surface of mercury when at rest should be very bright and almost invisible, and small globules, if detached, should be perfectly spherical, and not adhere to the glass, but roll over it freely when the surface is inclined.

UTILIZATION OF THE SUDS FROM THE WASHING OF WOOL.—In nothing has the advance of practical science been more clearly evidenced than in the extent to which substances formerly wasted and lost are now reclaimed and made to constitute an important element in the profits of the manufacturer. One of these applications consists in the recovery of the soapsuds from the washing of wool in woolen factories. These were formerly allowed to run down the sewers and into the streams, to the great pollution of the latter; but in Bradford, England, they are now run from the washing bowls into vats, and there treated with sulphuric acid. The fats rise to the surface in a mass of grease a foot or more in thickness, which is carefully collected and treated in various ways, mostly by distillation. The products are grease, used for lubricating the cogs of driving wheels in the mills; oleic acid, which is worth about \$160 per ton, and used as a substitute for olive oil; stearine, worth \$400 per ton, etc. It is said that some large mill owners are now paid from \$2,500 to \$5,000 a year for these suds, which a few years ago were allowed to run to waste.

TAR WALKS.—A correspondent recommends the following mode for making tarred walks: First gravel the walk in the ordinary way, but do not give it so thick a coat as usual; beat well down to make a perfectly smooth and even surface, which coat well with tar. When this is done put the final layer of gravel on the top, three-quarters of an inch to one inch will be quite sufficient, and again beat down, using the back of a spade for the purpose. The walk so prepared must not be trodden upon for two or three days, at the end of which time it will have become perfectly hard, and will not be affected by the heaviest fall of rain. The work must be done in fine weather, and the plan will be found better than using cement mixed with gravel.—*English Mechanic*.

SHAM COFFEE.—We learn from a statement in the *Journal of the Chemical Society* that sham coffee is manufactured from tough dough, squeezed into little molds and baked until the color becomes dark enough to deceive the eye. Real coffee berries, when small and worthless, are improved in color by rolling them about with leaden bullets in a cask. The green berries, too, are treated by a coloring matter. In coffee sold really ground, the difficulty of detecting adulterations is greatly increased; beans, beet root, carrots, and carrot-like roots are roasted and mixed in large quantities with the genuine article. In the south of Europe, especially in the provinces of Austria, figs are roasted in enormous quantities and sold as coffee.

COW HAIR AS A SUBSTITUTE FOR WOOL.—There is now being manufactured in England a class of goods known variously as velvets, Ulster coatings, chinchillas, etc., alleged to be made of hair and vegetable fiber, without the admixture of wool in any shape. These goods are finding their way into the United States, and the custom house authorities are not a little puzzled as to where to place them, when scheduling them for duty. Testimony of experts was called in; but it was only another case in which "doctors disagreed." The solution of the problem has been made the duty of the National Academy of Sciences.

SAVE YOUR SOAPSUDS.—Who would throw away a barrel full of soft soap or a box of hard soap? Were it not otherwise useful, it would be of great value as a fertilizer. But, after being dissolved in water and passing through the wash tub, gleaming the imperceptible elements of the best manure from soiled linen, its fertilizing power is vastly increased. Indeed, we may almost say that the average soapsuds from the kitchen and laundry is worth more than the soap which produces it.

DOMESTIC ECONOMY.

FANCY MATS FOR FLOORS.—Take a piece of canvas, of size desired, such as coffee sacks are made of. Cut a quantity of black and colored cloth in circles of various sizes, making sufficient, when one is laid on top of another, to cover the entire mat. Sew the large lower ones down on the canvas, and the upper ones keep in place by taking four stitches from the center across each side, using coarse colored cord or twine; finish by making tufts of ravelled carpet, yarn, or zephyr on the top on the top of each cluster of circles, using various bright colors. To make these, pass a strand up through the center, and winding a quantity around two or three fingers or a piece of card, lay the bunch across the top of a circle, and passing the needle and strand down through it again (near the spot where it was drawn up), pull it firmly down until the tuft is drawn together, when fasten by taking a stitch or two on the under side, and proceed to the next circle. When all are done clip the tufts into round half balls or battons. These mats may be made of old cloth, and are not only very handsome but durable. Another good mat is made by taking a piece of Brussels or ingrain carpet for a center, then finishing with a border of cloth of any and every description, plaited together in broad bands, and sewing this long piece and braided strip round and round the mat until of desired size. Coffee sacks, worked in with coarse yarn or strips of bright cloth, making figures, flowers, etc., are really handsome when carefully done.

A HOME-MADE CARPET.—An Eastern lady says: Have any of you a spare bedchamber, seldom used, which you would like to carpet at little expense? Go to the paper-hanger's store and select a paper looking as much like a carpet as you can find. Having taken it home, first paper the floor of your bedroom with brown paper, or newspapers. Then over this, or these, put down your wall paper. A good way to do this will be to put a good coat of paste upon the width of the roll of paper and the length of the room and then lay down, unrolling and smoothing at the same time. When the floor is all covered, then size and varnish. Only dark glue and common furniture varnish may be used, and the floor will look all the better for the darkening these will give it. When it is dry, put down a few rugs by the bedside and before the toilet table, and you have as pretty a carpet as you could wish; a carpet, too, that will last for years, if not subject to constant wear, and at a trifling expense. I myself used a room one entire summer prepared in this way—used it constantly; and when the house was sold in the fall, the purchaser asked me to take up the oil cloth, as he wished to make some alterations which would be sure to injure it.

BE ECONOMICAL.—"Take care of the pennies." Look well to your spending. No matter what comes in, if more goes out you will always be poor. The art is not in making money, but in keeping it. Little expenses, like mice in a barn, when they are many, make great waste. Hair by hair, heads get bald; straw by straw, the thatch goes off the cottage; and drop by drop the rain comes into the chamber. A barrel is soon empty if the tap leaks but a drop a minute. When you mean to save, begin with your mouth; many thieves pass down the red line. The ale jug is a great waste. In all other things keep within compass. Never stretch your legs further than your blenket will reach, or you will soon be cold. In clothes, choose suitable and lasting stuff, and not tawdry fineries. To be warm is the main thing; never mind the looks. A fool may make money, but it takes a wise man to spend it. Remember, it is easier to build two chimneys than to keep one going. If you give all to back and board, there is nothing left for the savings bank. Fare hard and work hard when you are young and you will have a chance to rest when you are old.

WASHING DISHES.—A housekeeper makes the following suggestions: I have large dish pan, small dish pan, and a basket made of ordinary splint. It is two feet long, a little over one foot wide, ten inches high, strong sticks across the bottom, and handles at the ends. After placing the old sack in the bottom of my basket, I pat over it a crash towel and turn down my dishes in the basket; cups at the ends, plates in the center, and covered dishes, glass, etc., on top. Finish all my other work, as suggested, and take my basket to the china closet, near the shelves. I go over them slightly with a linen towel, and they shine like—well, washed china. My basket was made by a Canadian 15 years ago, and cost me 50 cents. I could not wash dishes without it. Think of the steps it has saved me in that time. Besides drying the dishes in it, I often place all my dishes for setting the table in it and carry in one journey to the table.

APPLE FLOAT.—A pint of stewed, well mashed apples; whites of three eggs, four large spoonfuls of sugar, beaten until stiff; then add the apples and beat all together until stiff enough to stand alone. Fill a deep dish with rich cream, boiled soft custard, and pile the float on top. This is excellent with other fruits in place of apples.

GOLD CAKE.—Two cups of flour; three-fourths of a cup of butter; one egg and the yolks of eight eggs; two spoonfuls of baking powder.

PERKINS' PATENT SELF-REGULATING WIND-MILL has now been in use some five years in California, and is highly recommended. Israel Horton, the general agent for this co. st. at Livermore, has been busy in disposing of them in large numbers in the San Joaquin valley and other adjoining districts of California, and has not hitherto introduced them through the Press to the general farming public of the State. On a recent visit to Livermore, we found Mr. Horton to be a well established business man, and we expect to see his already successful business extended to various new parts of the State. His windmills have taken the premium at both the San Joaquin Valley agricultural fair at Stockton and the State fair at Sacramento. Persons wishing windmills are referred to Mr. Horton for his illustrated circular.

A MINER named Samuel Mugford was instantly killed last Friday afternoon while at work in the Garfield mine, near Amador City. Deceased was a native of England and 42 years of age. He leaves a wife and five children.

The famous Bowers mansion, in Wasboc valley, near Frankton, will be sold at public auction on the 3d of May next. Evidently the propheying business has not paid Mrs. Bowers, says the Virginia Chronicle.

PARK still declines to answer questions as to the amount realized by him in the Emma mine transaction, and the committee are divided in opinion as to their amount.

BARNEY WILLIAMS, the well known actor, is dead.

Railway for Transporting Freight.

Phineas Benning, of Wilmington, Los Angeles county, has recently patented through the SCIENTIFIC PRESS Patent Agency certain improvements in railways and the carriages employed thereon, by which he is enabled to lay a line of road and operate it over a country where but little grading is necessary, so cheaply that it can be made available for the transportation of freight, lumber, and in some cases passengers, in thinly settled districts where an ordinary line of road would be too expensive. It consists mainly in a peculiar construction for a permanent way and for the carriages which are to run thereon, and merits a detailed description as a novelty in engineering.

The improved road is designed to be constructed where timber is plenty, and for this purpose a portable sawmill may be first taken into the forest, where the lumber is cut into planks about three inches thick and of any suitable width—fifteen inches in width where the timber will serve, and of any length; these serve as a track when laid. Similar timbers are also cut of such a length as to answer for cross-ties. Usually these can be made of the outside slabs sawn from the logs, and they are laid upon the road bed, which is then filled up with earth and tamped, so as to be level with these ties. About 2,000 of these ties may be employed per mile, and the planks are then laid two in width, side by side, and breaking joints, so that the track when laid will present a solid surface from 20 to 30 inches in width. The lumber of the track should be properly out, so that when laid the grain of the wood will stand nearly vertical, to reduce the wear to a minimum.

The carriage which is intended to be used in combination with the road is made in any form suitable for the load it is to transport, and is mounted upon trucks. The wheels or rollers which are employed are of peculiar construction, and are intended to be employed especially in combination with this peculiar road. These rollers may be made of wood or iron, and have flanges at their outer edges by which they are prevented from leaving their track. The axles of these rollers may be extended so as to carry cranks beyond their journals, and the driving engines will be connected to those cranks in any suitable manner, so as to drive them.

It will readily be seen that in some cases the drivers or rollers might be made in pairs upon the same axle, and sufficiently separated to allow the cranks to be formed between them, but slight modifications of this sort will readily suggest themselves to those who construct the road. It may be found desirable in some cases to cover the rollers with rubber or other elastic substance.

The rate of speed to be allowed will be low, and the road is only intended to be constructed over sandy or heavy land, which is tolerably level, and to be graded at a low expense, and where the expense of a wagon or railroad would be large. If a pine forest is easily accessible at either end or near the proposed line the lumber can be procured at from five to ten dollars per thousand feet, and by utilizing the outer slabs of the logs for the cross-ties, about fifty or sixty thousand feet per mile will be amply sufficient for the construction of the road, which would then cost only from three to five hundred dollars per mile, exclusive of rolling stock, etc. If desired, the road when finished may be coated with asphaltum or suitable material, but this is not essential to its success.

UNFORTUNATE CHEMICAL EXPERIMENT.—In September, 1870, while Professor Thomas Price was lecturing under the auspices of the Mechanics' Institute, in this city, an explosion of certain gases took place. The Professor and his assistant were severely burned, and one W. L. Urton, a spectator, had his eye put out. He sued Professor Price for \$25,000 damages, asserting that the accident occurred through his carelessness or ignorance. The suit has been pending for a long time and has excited considerable interest, but a decision was arrived at this week. The jury brought in the following finding: That the defendant was the servant of the Mechanics' Institute and not responsible; that he had not used all the precautions against action now known. On the latter point the court sent the jury back to determine whether the defendant had or had not used all the precautions against accident known at that time. The jury then retired and after two hours' deliberation returned a verdict for the plaintiff, and assessed the damages at \$500.

A RIDE TO NEVADA CITY.—We are indebted to Mr. Chas. Barker and lady, of Grass Valley, for a pleasant ride between the above named places. Prominent evidences of improvements were observed on the route, including the Fryer reduction works and the Gold Race-track homestead, lately purchased by the Fryer Co.; V. flame company's terminus works on the divide, near the narrow gauge tunnel. The Idaho mine, under the superintendence of Mr. Coleman, is hoisting, crushing and successfully reducing between 500 and 600 tons of ore weekly, with as little noise and friction as any well regulated quartz mill and company can get along with. Nevada City still holds its leading position as one of the finest and most permanent mining and business towns in the State.

Paul's Dry Process.

This process and machinery connected therewith, on which Mr. Paul has now secured some eight patents, the 1st of which was issued through the SCIENTIFIC PRESS Patent Agency some weeks ago, is finally to be practically illustrated in San Francisco by a mill of a capacity for testing ores by the ton. Unlike most new processes, which generally start in the city and die out in the mountains when they are put to the test of practical operations, this has been fully perfected, Mr. Paul tells us, through the working of thousands of tons by large mills. Taking these facts, together with Mr. Paul's 25 years or more of practical experience in gold and silver mining, we feel safe in saying that this mill will be worthy the examination and attention of all engaged in quartz mining. Mr. Paul's claims for his system have been very broad and fully proved up, publicly, as he now proposes to do, there is certainly a great future for our gold quartz mining interest. Mr. Paul's claims, among others, are as follows:

That it will work gold ores and gather flour gold with the same readiness as the coarser, whether free or associated with iron, copper, lead, antimony or zinc, or all together in one matrix, and produce bullion free of any or all of the base metals, less natural alloys.

That it will produce from 10 to 100 per cent. more metal than any known system of amalgamation working at the same expense.

That where silver is associated with a large percentage of lead, copper, zinc or antimony a certain percentage can be extracted in fine bullion—the percentage owing to ore—say from 20 to 85 per cent. The residue in base metals can be taken up by concentration, at no additional expense except for machinery.

That it will work silver ores carrying any of the base metals to a higher percentage than any system of raw amalgamation, and produce bullion 950-1000 fine.

One of the most remarkable features of this system of dry amalgamation is that no base metal is taken up with the precious under any circumstances.

A CENTENNIAL QUARTZ MILL.—John Reardon & Co. have nearly completed, at the Union Iron works, Sacramento, a very complete model quartz mill, which they intend exhibiting in various cities in the Union and at the Centennial. The stamps are of one-third the usual diameter, with all other fixtures of corresponding size. It comprises four batteries of five stamps each, sluice blankets, amalgamating plates, boxes, grinding and settling pans, etc., forming altogether a novel but complete working mill. It is accompanied by a very neat two horse-power engine. We expect to give further particulars of Mr. R.'s plans soon. The same foundry recently received an order for a first-class ten-stamp mill for a mine in Plumas county. The works are fairly busy on agricultural machinery and general jobbing. Among the recent California inventions machines constructed in part by the proprietors, is Miller's new hay press, for which Marcus C. Hawley & Co. are agents.

STAGE CHANGES.—On Monday of last week the narrow gauge railroad relieved the faithful drivers and wearied horses on the stage line between Grass Valley and Colfax. Mr. C. J. Shaw, who has been the active agent of the line at Colfax since 1865, will also take a rest. He informs us that the year before the narrow gauge was determined upon 10,005 passengers went over the road to Grass Valley and Nevada. During the flush times of travel on the route he estimates the number of passengers as high as 20,000 in a single year. Over 70 Chinamen are now at work on a new stage road from Colfax to Yankee Jim's, over which passengers will be taken for Todd's valley, Forest Hill and Michigan Bluffs, perhaps as early as July next. This will shorten the stage route to Yankee Jim's one-half. This will add again to the stage business of Colfax.

TELLURIDES.—At the last meeting of the San Francisco microscopical society, Dr. Jas. Blake presented a slide, mounted with gold, which he had obtained from so-called telluride of gold, by treating with acid. The telluride was obtained from the American mine, Sunshine district, Colorado, and showed no gold before the application of acid, and Dr. Blake stated his belief that the pure gold was simply concealed by a superficial coat of tellurium, which was a decided case in favor of the assumption by Mr. Hanks, which he had offered at a former meeting, that there was no chemical compound of gold found in nature, or, in other words, as he then stated in his paper on "Micro-Mineralogy," "the results of my microscopical examinations cause me to doubt if gold ever becomes mineralized, in the strict sense of the term."

LIBERAL TERMS FOR CITY REAL ESTATE.—We would call especial attention to the advertisement of real estate at auction in Oakland in today's issue. City and country residents who wish to secure lots in Oakland at extreme low and favorable rates should not let the chance of securing property in that desirable city pass. Examine the property and be prepared to buy when the day of sale comes.

Gems and Precious Stones.

(Written for the Press by HENRY G. HANKE.)

(Continued from last week.)

Diamond cutting not only requires great skill and judgment, but also requires the outlay of considerable capital. The largest establishments for this branch of industry are in Amsterdam. In the year 1872 I visited the works of M. & E. Coster, in that city, and saw the whole operation. The building is a large brick structure, every part of which is devoted to some branch of the trade. A beautiful and powerful engine in the basement drives the machinery. Vertical shafts pass up to the top of the building, and from these the grinding discs are geared.

I was first shown the room where the diamonds are kept for safety, and had the opportunity of seeing some fine stones. From this room I was shown to another where the stones are split. This is a curious and delicate operation. Only workmen of great experience are allowed to attempt this work.

The rough diamond is taken up by one of the workmen in this room, who studies it carefully, calculates mentally what parts can be removed without detracting from the value of the stone, keeping in mind the rule already stated, that the value of a rough diamond is only that of the largest doubly truncated octahedron that it will make. All excess must be removed. It is a great advantage to split off fragments, for the double reason that, the larger fragments may be cut with profit into small stones, to set around opals or pearls, and because it is a great economy of time, as the grinding down of the stone is a slow and tedious operation. It sometimes becomes necessary to remove flaws by this operation.

The workman is well aware of the fact I have already stated, that the cleavage of the diamond is four-fold, and takes every advantage. It is astonishing to witness the skill with which they perform this operation. A workman cements the stone to a piece of compact wood by means of a strong cement, leaving the portion to be removed exposed. To this end he fashions the cement with his fingers while still soft, then with a fragment of another diamond he makes a deep scratch along the line of cleavage. Then, after wrapping the stone in loose folds of cloth, he applies a steel rule or knife edge, with a gentle and skilful blow with a light rod of steel he breaks off the portion he wishes to remove with unerring certainty.

From the hands of this workman the stone passes to another in another room, who continues the operation by cementing it again to the end of a stick and taking another diamond of equal size, also cemented in the same manner to a stick; he rubs the two together until he produces the proper facets on each—each grinding the other down, literally "diamond out diamond." The workman to whom this operation is entrusted wear heavy leather gloves. The powder resulting from the abrasion is carefully collected in a box, in which oil is kept which collects the dust and prevents it from being blown away. When sufficient has collected the oil is burned away, leaving a gray powder called "bort," which is more finely powdered and used to polish other diamonds. During the operation of grinding the workman frequently touches the stone to his tongue to see how the operation progresses; first, however, removing any adhering diamond dust with a camel hair brush. This work does not form all the facets of a perfect stone.

The next and last operation is that of polishing the rough cut stone and of cutting away some of the edges, producing a new set of facets, due to a perfectly cut brilliant.

The polishing is done on discs of iron or steel. These wheels are about three feet in diameter and rotate horizontally. They move with great velocity, making 2,000 revolutions in a minute. They are so true and run so smoothly that at first glance they seem like stationary tables, sustained by the vertical shafts. It requires some skill and labor to prepare the surface of these discs to render them suitable for receiving the diamond powder. Stones of varying fineness are used in such a manner as to leave striations on the surface, something like that of the barr mill stone, but very much finer. A mixture of diamond dust and olive oil is then placed on the face of the disc, which is called a "skaif." The workman then takes a brass tripod, of which one arm is longer than the others; in the end of this longer part there is a socket, which he fills with melted solder, into which, as it cools, he imbeds the stone, leaving the face only exposed which he wishes to polish. When the solder is perfectly cold and hard he turns the stone down on the revolving plate, allowing the shorter arms to act as a claw to hold against the friction of the wheel. He then puts weights on the end of the tripod above the stone. These are heavy or light as the face is large or small.

The Amsterdam establishment employs from 500 to 600 persons, who are mostly Jews.

An establishment for diamond cutting has lately been started in New York, under the name of the New York diamond company.

For many years diamonds have been cut and polished in Boston, and quite recently the English have turned their attention to the art they once excelled in. An African diamond has just been finished in one of these works which is highly spoken of. It is said to be a most magnificent stone.

The Kohinoor was cut in London, but by some of the skilled workmen from Amsterdam.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency the following are worthy of mention:

GUARD FOR SHAPING MACHINES.—Marquard Hansen, S. F. The object of this invention is to provide a fender or guard for protecting the hands of workmen from being cut or mutilated by the shaping machines which are used for shaping and trimming pieces of wood. These machines consist of two or more horizontal blades secured to an upright shaft just above a table or bench and rotated at a high rate of speed, so that it is often impossible to distinguish the blades or cutters; consequently workmen are frequently injured or maimed by bringing their hands in contact with them. This invention is a guard or fender which can be adjusted so as to permit the workman to use the machine without danger of bringing his hand in contact with the cutters. In the upper face of the table, at a proper distance from the shaft, is snubbed a curved metallic plate so that the shaft will be the center of the curve and therefore equidistant from every part of it. In this plate are bored two or more holes at suitable points, and these holes are tapped with screw threads. A post is made with a screw on the lower end which will fit into either of these holes. A horizontal bar is then taken, provided with a hole of sufficient size to allow it to slip down upon the post, so it can be fixed at any desired point by a set screw, while the other end is formed into a ring which slips down over the upright cutter shaft. A fender band or guard is secured to this horizontal bar so as to encircle the shaft and cutting blades. This band is adjustable back or forth by being attached to the bar in the manner of a slide, so that part of its circumference which is opposite the slide can be moved to or from the rotating cutters and thus not only gauge the block of wood to be trimmed, but also protect the hands of the workman from being cut by the cutters. The band can easily be raised or lowered. Should the screw post be in the way of the workman, it can be shifted to different holes and thus prevent the device from interfering with the work. This gauge and guard is quite simple in construction and will effectually protect the hands of workmen from this heretofore dangerous machine.

DOUBLE BEARING BRIDGE FOR PIANOS.—Jacob Zech, S. F. This invention is an improvement in the construction of pianos, and consists in a novel bearing bridge, in which Mr. Zech forms a continuous and solid bearing for the strings, and so secures it to the wrest plank that it is entirely free from contact with the iron frame of the instrument. By this construction he avoids, first, the use of a number of separate pins or supports for the strings, each of which must be separately secured; and, secondly, he does away with a disagreeable tone which is produced by the necessity of securing these separate supports to the iron frame itself. The improvement consists in the use of a continuous brass plate, having projecting lugs at suitable intervals, through which angular holes are bored to receive the strings. This plate may be made of any length suitable for the positions which it is designed to occupy in the instrument, and is formed with the front of the plate extending down the face of the wrest plank, to which it is securely fastened. A projection is formed with this plate and extends back at right angles with it beneath the frame. An arrangement is also made so that there will be no contact between the bridge or any portion of it and the frame. By this construction Mr. Zech claims to greatly improve the tone of the instrument, and is enabled to make a solid and substantial bridge which is of superior durability to the present method.

IMPROVEMENTS IN PLOWS.—Jas. T. Watkins, Santa Clara. This improvement in plows consists in constructing the share and landside in one single piece and in providing a simple and extremely effective means for attaching it to the standard and mold board, so that the share and landside can readily be removed for sharpening or other purposes when desired. It is not new to make the share and landside of a plow in one single piece and secure them by means of bolts to the mold board and standard. Neither is it new to make the share so that it can be attached to the mold board and detached from it without the use of bolts; but this invention differs from both of these devices. A detailed description of the improvements would not be intelligible without the aid of engravings.

PROCESS FOR CURING TOBACCO.—John R. Opitz, Anaheim, Los Angeles county, Cal. This is a novel process for curing the leaves of tobacco without removing them from the place where they are grown, and without transferring them to drying houses. The inventor calls it the "California underground process." He claims that tobacco cured by this process will be found with unbroken leaves and as soft as silk, while it will be of a very even color. Moisture enough will be found in each leaf to steam and assist in curing it and the covering of each will prevent the sun from burning it. The earth also has the property of extracting from the leaves a certain unpleasant and bitter

flavor which is found in many kinds of tobacco, and by other means the juices from the stalk are prevented from running down into the leaves, as happens in drying houses. By this method all cost of drying houses and much of the cost of gathering and transporting the leaves and the consequent tearing of many of them will be avoided. The expense will be reduced to fully one-half what it is by the old process. The process is especially valuable to countries which have rainless seasons and may be there employed, as there is no danger of spoiling the tobacco by dampening.

IMPROVEMENT IN SHOES.—Conrad Glanville, S. F. This invention relates to no improved mode of forming welts and stays for protecting the seams on boots and shoes, and it consists in utilizing the single edges of a doubled welt so as to make them serve as stays on the outside of the seam. The seam to which this welt is applicable is the manufacture of boots and shoes is when two raw edges are to be united together. Instead of using a single thickness of leather to form the welt, this inventor takes a strip of leather, cloth or other material of which the welt is to be made, and folds it double lengthwise; and in applying it he places the doubled strip between the edges to be united, and sews it in place so that its doubled edge will project slightly on the outside, while its single edges are on the inside of the seam. He then folds the single edges of the stay piece in opposite directions, and sews them down by a row of stitches on each side of the welt so that their inside edges will form a stay for the seam. An independent stay piece can be used if desired, but when it is used the inventor places it over the inside of the seam after the edges of the stay piece have been folded back; and the same row of stitches which fastens the edges of the stay piece down will serve to secure both the independent stay piece and the edges of

The Black Hills Fizzle.

"The latest reliable news from the Black hills is that nine Montana miners, who have been working steadily in the hills for the past six months, have averaged just \$10 per month to the man, having taken out \$540 for their six months' labor." This is the class of items one sees going the rounds of the press now-a-days, and they are somewhat different from those which appeared six months since. We are happy to remember that we never fostered the excitement in the least, but advised our readers to stay at home if they had anything at all to stay for; but at all events to wait. The evidence is accumulating that the Black hills country, as a mining region, is a fraud. The traders of Cheyenne have kept up the excitement as long as possible. The truth is now pretty well ascertained, in spite of preventive efforts. This is not by any means the first instance where the traders and carriers have kept up similar excitements, but in this instance the thing was well worked up.

It is now stated that the authorities at Fort Leavenworth are believed to be in possession of information which, if made public, would stop all emigration to the Black hills. Great trouble by Indians is apprehended. About 10 days ago three wagons were found at the entrance to Buffalo gap, on the Yankton route to the Black hills, nearly destroyed. The stock was gone, the wagon covers had been shot to pieces and the material which the wagons had been loaded with was lying around, some with marks of balls on them. Indians had evidently attacked and destroyed the entire outfit. Another dispatch from Fort Laramie says a party of immigrants were attacked by Indians on the 16th inst., near Cheyenne River rancho, about 50 miles from Custer. A few of the party escaped

An Improved Quartz Mill.

In a recent issue of the Press we mentioned that Messrs. Cowles & Cooper, of Sacramento, were building several of the improved California Giant quartz mills, which would shortly be in operation on mines in this State. As the mill possesses some new features, we herewith describe it in detail, with an illustration. The engraving is not our own and is not so fine as desirable; moreover, since it was made some slight changes in construction have been introduced, but it will serve to give the reader a better idea of the machine than a mere verbal description. Probably at some future day we shall give a more complete drawing by our own artist.

The mill itself is an improvement of the old Mexican alastra and the Chilean mill, by which means both a crushing and grinding of the quartz is effected and the defect of much loss of power is avoided. The power is applied to the periphery of the crushing wheel instead of the center, an improvement which any one can see the importance of.

In the mills now being built the crushing wheel, marked C, in the engraving, is 12 feet in diameter and 18 inches wide.

Three-inch hard iron plates are firmly bolted to the periphery of the wheel, the whole revolving around in a sectional iron disk or pan, M, which is securely bolted to the flooring. The wheel, C, is kept in its revolving course by the horizontal shaft passing through an elongated slot in upright post, E, which post revolves into a suitable step or bearing, in the center of amalgamated plates, G. The horizontal shaft passing through crusher wheel, C, is properly secured by a washer with a set screw to keep said wheel to its center, and prevent its going out of its regular course. The upright post, E, is also connected at the top by passing through a boxing on the cross beam, B. The power is communicated from the engine, or other power, to the fly-wheel and shaft, H, with its geared pinion to the gears on top of the crown wheel, D, on the side of which is another set of gearing which meshes into the gearing on the crusher wheel, C; thus making a compound leverage in the application of power. As the manufacturers have a 12 foot leverage from top to bottom of the crushing wheel, eight and a half feet the diameter of the crown wheel, eight inches in the diameter of the pinion and a four foot leverage in the driving wheel, by applying the power on this principle they claim to be able to crush 35 tons per day of hard flint quartz, with from six to eight horse-power.

The crushing wheel weighs, when complete, 12,000 pounds and the whole machinery is placed upon heavy trestle work. In rear of the crusher wheel, C, steel plows, L, are placed at convenient intervals, which stir the pulp in the pan, M, to prevent packing, and to more effectually allow the water, with the aid of the wash board, K, to carry off the superabundant pulp which may collect in the pan, M, through the screens on to the amalgamating plates, G. The wash board, K, works on the principle of a huge hinge in the bottom of the pan, M, by rods running up to the horizontal shaft passing through the crusher wheel, C, which motion is produced by a ratcheted cam on the shaft, relieving the mill of its pulp much quicker than through the stamp mills. The hopper, J, is for the purpose of more effectually carrying the rock and depositing it into the center of the pan, M, where it is crushed by the wheel. Around the whole is a platform sufficiently large for the shovelers to stand upon to feed the mill. The above dimensions are calculated for a mill of a 35-stamp capacity, to be driven by a six and eight horse-power.

The mill is now built with screens for the outer as well as the inner surface, and is also provided with agitators for driving the pulp against the screens. The mill now building at Gutenberg & Co.'s foundry, Sacramento, will be a ponderous crusher as well as grinder. The shoes and dies are of white metal, and our examination of the castings showed them to be very heavy and strong. Mr. Cooper is an energetic man and he has studied into the mill business differently than most men do. We see by the last Calaveras Chronicle that the mill for the Boston company's mine, near Buckeye, which is one of this pattern, is now on the ground. A hurdy gurdy wheel is to drive the mill.

For miners working their own mines this mill appears to be very advantageous. It is made of all appropriate sizes. The manufacturers state that they will put these mills up to any desirable capacity to suit large properties. This quartz mill makes very little noise while in operation and it grinds the ore very fine. It can be run by water, steam or horse-power. The gears on the crushing wheel now are not beveled, so that it can raise or lower a short distance without interfering with the gearing in the least. Altogether the mill appears to be pretty effective and we will not be surprised to hear of its achieving very good results on a large scale. Messrs. Cowles & Cooper, of Sacramento, are the manufacturers.

Parties interested in this class of machinery should examine the merits of this mill, for which those most acquainted with its working claim most remarkable results.

THE CALIFORNIA GIANT QUARTZ MILL.

the welt piece. Mr. Glanville thus provides a doubled welt which will not only look neat in appearance but will project slightly above the cloth and protect the stitches upon each side from the wear to which they are subjected by the friction of the lower edge of the dress of the wearer chafing over it, and at the same time the welt piece forms a stay for the seam, both welt and stay being combined in the same piece or strip of leather.

GLOVE MANUFACTURING.—This branch of home industry is a success in California for very good reasons. When the best of California dressed skins are used, customers can depend upon a better article for wear than can be obtained of any imported article. From a recent call at I. W. Lusk's "Sacramento Glove Factory," on 10th street, between J and K streets, Sacramento, we learned that ladies' and gents' driving and other gloves were made of black kid, russet, and drab, and Indian tanned buckskin. Mittens are also made for boys and girls—old and young. Singular as it may appear to Northerners, the busy season in this trade is during the warmest part of the year, from May to November. This is on account of mining, teaming, harvesting and other farm work prevailing during the summer months. To obtain a correct measurement for the glove maker, place the palm of the hand on a piece of paper, spread the fingers well apart and mark around them with a pencil. Measure around the palm of the hand and mark the circumference on the penciled figure, and you are guaranteed a fit from any such a pattern. Mrs. Lusk informed us that the above named factory (formerly owned by W. F. Ashby,) has been established over nine years. The work is done principally by ladies, and we wish the enterprise continued success.

CALIFORNIA CARRIAGE MANUFACTURING CO.—Messrs. W. L. Pritchard, George Cowles and C. Zimmerman, have established in Sacramento what is now the largest carriage factory on this coast. The building has four stories, fronting 168 feet on Eighth street and 88 on K street. Cost, \$100,000, including the lot. They have the latest improved machinery, systematically arranged for turning out good work economically. This home enterprise is worthy of future notice in our columns.

to the rancho. Mr. and Mrs. Metz, of Laramie City, were killed, and a colored woman taken prisoner. A man named Simpson was also killed. Three men were wounded—Grichan, from Missouri, mortally; Felton, from Maine, and W. Bergessir, from Virginia City, Nevada, seriously. It is feared their wounds may prove fatal. The wounded men are at Cheyenne River rancho. The place where the attack was made is about 120 miles from Fort Laramie. Altogether, those who did not go to the Black hills can congratulate themselves on being wise enough to stay at home.

THE SILVER QUESTION.—The long looked for and anxiously expected speech by Senator Jones on the silver question was made this week. The telegraph has brought us only a summary of the speech, but as it is said to fill 61 columns of an ordinary paper, it will come better by mail. Senator Jones wants a return to the double standard of gold and silver. His arguments are very comprehensive, and cover a great deal of ground. In fact, it would be impossible to criticize it at all without reading the speech entire, which we shall take pleasure in doing on its arrival by mail.

BISMUTH.—"H. H." writes us from Franktown, Nevada, describing a mineral he supposes to be bismuth, and asking us to give him some description of the occurrence, etc., of bismuth; and also, to decide whether the mineral he describes is really bismuth. If "H. H." will send us, post paid, a specimen of the mineral in question, we will determine its character without any expense to him, but are unable to give any definite opinion from the meager description received.

Dr. J. THOMAS JOHNSON will represent the Press in Virginia City and other parts of the State of Nevada on business and editorial matters. Our friends will find him a true gentleman, and we invite them to assist him in his laborious efforts for the mutual advantage of the community and our paper.

EX-ATTORNEY GENERAL BUCKNER, of Carson, has completed the sale of the Montezuma mine, in Humboldt county, to San Francisco men, for \$30,000.

Another Mechanical Miracle.

The credulity with which intelligent journalists accept as true the most extravagant and impossible statements concerning new inventions, indicate a degree of simple faith and an abiding trust in human nature which is not often found now-a-days, except among holders of Keeley motor stock. The latest "invention" of this kind is a device for producing unlimited heat by burning seven-eighths water and one-eighth of something else mixed with it. The Chicago Times thus heralds it to the world:

"Yesterday we were shown what promises to be the most wonderful invention of the age, and one which promises to revolutionize our entire domestic economy. It is nothing less than a substitute for fuel, produced at comparatively no expense, and by the application of the simplest scientific contrivance. The invention is denominated the hydro-carbon burner and gas generator. By the application of the invention, ordinary coal oil and water may be made to produce heat enough to run an engine, propel machinery, heat a cooking stove, illuminate a mansion, or perform any other result usually accomplished by means of wood or coal. By its use the most difficult mechanical problems are to be solved in the future. The burden of gas monopolies will be abolished, and the new system of generating heat from water and oil will astonish the scientist as the unschooled and undisciplined mind. The process is not complicated or mysterious. It is simply the result which overwhelms the mind with its wonderful possibilities. Prof. Kendall, the well known chemist, who has experimented with this invention, says that all the fire to do the cooking and washing for six persons seven days can be produced for 50 cents. The apparatus burns from one-fourth to seven-eighths as much water as it does any other combustible fluid, and produces a result which cannot fail to fill every one with amazement who witness its operations. For household purposes it is unexcelled. There is no dust or filth, smoke or disagreeable scent about it. Gas can be furnished from any cooking stove to illuminate a house for 50 cents per thousand feet. The light produced is clear, bright and steady, far superior in quality and illuminating properties to the ordinary gas produced from coke, which costs from \$3 to \$3.50 per 1,000 feet. The attachment can be made to any stove, range or furnace, or motive power, with entirely satisfactory results. A patent has been procured, and the inventor, a very eminent scientific gentleman, is now prepared to enter the field, and capture the public with an invention, obvious on sight, and more useful to civilized man than could be the realization of the wildest dreams created by the alleged claims of the Keeley motor, which have created so much comment and interest in the public mind. The simplicity and practicability of this apparatus can be determined on sight, and it is destined to go into general use as soon as its merits become known to the public. It has been examined by scientific men, and the principles of its foundation have been pronounced sound and in accordance with chemical science. Its discovery is more valuable to mankind than the alchemist's stone. By means of it the sufferings of the poor will be ameliorated and their sufferings assuaged. The inventor of cheap fuel may indeed be called a benefactor to his kind, and the blessings of the world will follow him. The genuineness and utility of this great and wonderful invention is destined soon to be acknowledged by the world at large, for truth is irresistible."

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

THE MINING AND SCIENTIFIC PRESS is the leading journal of America. New processes and mechanical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for \$4 per year. Dewey & Co., publishers, San Francisco. (Mt. Lincoln News, Alupa, Colorado.)

WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

BERRY & PLACE.

San Francisco,

Are the only Agents for sale of these
Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been
too long in use on the Pacific coast to require any special recommend-
ation from us. They are well known from Alaska to Mexico. We
would refer with confidence to any one of the hundreds in use. They
still sustain their old reputation, the manufacturers not having
followed the now too common practice of reducing the quality of
material and workmanship to compete with cheaper engines. They
have lately been greatly improved by adding large drums, and
reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Our new Mining Engine is built from plans
and specifications of several of our most
successful MINING ENGINEERS, and the re-
sult is the most complete

Double Drum Hoisting Engine

Ever built. Their advantages will be seen
at a glance by any one familiar with the
necessities of a mine. These engines may
be seen in use in Ophir, Con. Virginia,
Chollar, Europa, Niagara, Leviathan, Phil
Sheridan, and several other mines on the
Comstock Lode. For sale only at

Arizona.

MINE SOLD.—Arizona Miner, April 14: The mine known as the McKinnon & Oodwin, on the War Eagle ledge, Peck district, was sold on Saturday last by Rod McKinnon and John Goodwin to Wells Coe, of San Francisco, for \$10,000 in gold coin. We understand it is Mr. Coe's intention to sink 200 feet on the mine immediately, after which he will decide what to do next. This mine consists of a thousand feet along the War Eagle, and has been worked for two or three years by McKinnon and Oodwin as a gold mine by the process, and has always yielded good pay. So that now with the proceeds of this sale added to their earnings in the past gives them quite a handsome stake. It is believed that the War Eagle is an extension of one of the Peck series, and that at a depth sufficient to bring them on a level with the Peck they will find it to be a silver mine of great richness. The gold mines of all this region are prone to run into silver when the water level is reached, though this may be an exception to the rule, as in other cases the silver ores have been sulphureted in character, whereas the Peck and the Prince contain chiefly silver and carbonates. We had a talk with McKinnon on Sunday morning, and he informed us that he and Oodwin had other ground on the same ledge which they propose to develop, and which may prove as good as that they have sold.

THE MIDAS MINE.—H. T. Scott and A. Welsh discovered the Midas mine, on the east side of the Hasayampa, some seven miles below the old Sterling mill, and have recently started to assay the ore. They were in town Sunday and Monday with their first clean-up, some \$500 in very fine gold. The ledge is 12 feet wide where they are at work, and 30 in other places.

THE BLOELOW & THOMPSON TUNNEL.—On the 10th of January last Col. H. A. Bigelow and Oeo. S. Thompson started in on a contract to run a tunnel 240 feet on the Peck mine, working one shift of three men, and were to have all the ore they took out. They started on a small seam and took out a small quantity of high grade ore, which gave out, and they ran some 40 feet without finding anything until a week ago Saturday, when it came in again, and they are now running on the pay streak, which is widening as they approach the shaft.

Colorado.

MINING NOTES.—Colorado Springs Gazette, April 16: Owing to the unsettled weather and the snow on the mountains no prospecting and comparatively little work has been done in the way of developing the lodes before located in this vicinity the past week. The little that has been done, however, has gone very far towards settling the question favorably as to our having not only paying ores, but very rich ores of various kinds and in great quantities.

Much work is awaiting the result of the eight tons sent to Black Hawk from the Ute Pass mine, at Manitou, some weeks ago. This was treated on Wednesday last, but the result has not been received at this writing.

Box little work has yet been done on any of the lodes of the golden belt of Chama and Dog creeks, for reason of the snow. The little done, however, has been sufficient to establish their value in the minds of all who have seen them. The samples of ore shown us from the latest workings are certainly very fine, and would indicate strong veins. Rough tests of the quantity of silver contained in the galena, and in the shale lying between it and the hanging wall, have been made, and both show a considerable quantity of this metal. No trial has yet been had for gold, but an average of the pay streaks will be taken for assay in a few days. The belt is composed of a number of parallel lodes, with others crossing at nearly right angles.

A vein of honey-combed quartz has been found on the mountain west of Monument park 18 inches in width, which assayed by Prof. Schurmer, of the Denver school, showed a fine quantity of this metal. We do not know whether this is a fissure or contact vein, but from the appearance of the ore judge it to be the latter.

Several miners from Sunshine and vicinity are now at work here, and none are so confident of the value of the lodes of this region as they. They all agree that depth will reveal as rich tellurides as are found in Boulder county, and in very much larger seams. This must be determined by reaching the necessary depth on at least one location, before we can know that we have the same class of ores.

Idaho.

ATLANTA MINES.—Idaho Statesman, April 20: The mining developments of the past winter are of a more satisfactory and positive character than the labor of all the past years combined. The developments in the Monarch and Buffalo companies' works have established the fact that the Atlanta is a vein of the first magnitude, and inexhaustible in wealth. The recent strike in the lower tunnel of the Buffalo company, at a depth of 125 feet on the vein, has inspired a general feeling of confidence in the community. They struck the north wall of the vein proper some 400 feet from the surface, after driving thirty feet across the vein a streak of rich ore, some four feet wide, rewarded their efforts. In a few feet it increased to seven feet in width. I am not informed as to the value of the ore per ton, but am told that two feet and a half in width of the vein is recovered for shipping, which is a sufficient guarantee of its richness. Aside from the Buffalo and Monarch companies there are other companies running long tunnels to tap the Atlanta. On the Yuba side Messrs. Julian F. Hill and Wm. Abbott, of Idaho City, have run 170 feet of tunnel, which should strike the vein in 50 feet farther at a depth of over 100 feet. They have suspended work, however, to attend to placer mining in the Basin. For the information of those who think of coming here, I will say "grub" is scarce, consequently there will not be much done until the road is open.

Washington Territory.

THE MICA MINES.—Last Saturday Messrs. A. H. Simmons and J. D. Cook returned from a four months' prospecting and mining tour in the Coeur d'Alene mountains. During the greater part of their absence they were engaged in developing a ledge of mica discovered by Mr. Simmons several years ago. The mines are located on a spur of the Coeur d'Alene mountains, about seven or eight miles west of Lake Coeur d'Alene, in Stevens county. The altitude is about 4,000 feet. The vein at present being worked is about 10 feet wide; course from southeast to northwest; dip, about 60 deg. The foot wall is a hard semi-crystallized quartzite. The gangue is a micaceous schist, consisting of laminated mica and mica, the latter predominating. While the mineral assumes nearly all imaginable shapes, the favorite form, and in which the best material is generally found, is that of an irregular triangle, in which shape it is found in the schist and often entirely encased in the hard quartz, in pieces weighing 60 pounds and more. As to the extent and capacity of the mine at present we can give but little information, but it is believed that its resources are comparatively unlimited.

MAMMOTH POLISHED GRANITE COLUMNS.—The Union iron works, of Root, Nielson & Co., Sacramento, have recently manufactured to order the head blocks for an immense polishing lathe for Griffith, of the Penryn quarries. They are to be used in polishing the granite columns for the imposing front of the San Francisco Stock Exchange building, now being erected on Pine street.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SOLE TITIO PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. O., April 25th, 1876.

FOR WEEK ENDING APRIL 11th, 1876.*

PASSENGER REGISTERS.—Charles A. Washburn, Oakland, Cal.
FRUIT DRYERS.—William Aram, San Jose, Cal.
RUBY PIN INSERTS FOR WATCHES.—Carl H. E. Becker, Ocoville, Cal.
MOVABLE LOCKING TYPES.—William H. Bell, S. F., Cal.
CHIMNEYS.—Jeremiah Browell, S. F., Cal.
WHEEL PLOWS.—Edmund C. Brown, Antelope, Cal.
MACHINE FOR PACKING FRUIT AND OTHER ARTICLES.—George W. Deitzler, S. F., Cal.
SASH HOLDBERS AND FASTENERS.—William A. Hawthorne, Carson City, Nev.
COUPLINGS FOR TRAIN TELEGRAPH.—Andrew Ryder, Oakland, Cal.
COAL SCREEN AND SHUTES.—Byron La Count Satterfield, Charles L. Chrisman and James McKinley, S. F., Cal.
WATER WHEELS.—Moses M. Staples, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

OAKLAND, Saturday, May 13th, 1876

WOODWARD & TAGGART,

Real Estate Auctioneers.

R. A. COBB, AUCTIONEER, WILL SELL AT PUBLIC AUCTION, On Saturday, May 13th, 1876, at Salesroom, 460 and 462 Eighth Street, Oakland.

42 Choice Residence Lots, THE PROPERTY OF CHRISTIAN BAEOE.

This property is situated in a portion of the city that is improving as rapidly as any part of the city; is but a short distance from schools and churches; but four blocks from the Berkeley railroad, which is now being built and will be completed within 30 days. A station is to be built at the foot of Fourteenth street, which will bring this property within 30 minutes of San Francisco. There is not to be found within the city limits more desirable residence sites than this property presents. A horse railroad will soon be built in front of this property, which will bring it within five minutes' ride of Broadway station. Terms, one-fifth cash, one-fifth in one year, one-fifth in two years, one-fifth in three years, one-fifth in four years. Interest on deferred payment at the rate of 10 per cent. per annum. For further particulars, apply to

WOODWARD & TAGGART, 460 and 462 Eighth Street, Oakland.

MAURICE DORE & CO., 326 Pine Street, San Francisco.

NEW ASSAY OFFICE.

Thomas Price (formerly of the San Francisco
Assaying and Refining Works), having fitted
up the old Pacific Mail building, No. 524 Sacra-
mento street, corner of Leidesdorff, as an
Assay Office and Chemical Laboratory, is now
prepared to make assays of the precious and
useful metals and their ores, as well as com-
plete or partial analyses of all minerals, salts,
waters or other substances that may be desired.

His office will be opened for business on
Monday, May 1st, and he hopes that his long
residence and experience in his profession will
entitle him to a reasonable portion of the busi-
ness of his friends and the public generally.

THE O'HARRA

CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of
any gold or silver ores that are not more profitable for
smelting. Will also desulphurize ores and put them in
proper shape for working in cupola furnace.

Cost of Roasting and Chloridizing by this
Process:

Two cords of wood at \$6.....\$12.00
Two firemen at \$4..... 8.00
1500 lbs of salt at 15c..... 22.50
Wear of shoes and power..... 1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.93 1/2

In a furnace of three or four times this capacity the
cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe
Consolidated Co.'s mines, in the Peavine District. For
further information, apply to

D. J. O'HARRA,
Reno, Nevada.

will do well to recommend the publication
of the official notices of their companies
in this paper as the cheapest appropriate
medium for the same.

California Acclimatizing Society—Loca-
tion of principal place of business, San Francisco, Cal.
Notice is hereby given, that at a meeting of the Board of
Directors, held on the seventh day of April, 1876, an assess-
ment (No. 7) of fifty (50) cents per share was levied upon
the capital stock of the corporation, payable immediately,
in United States gold coin, to the Secretary, at the office
of the company, room 37, Nevada block, No. 309 Montgom-
ery street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid
on the seventeenth day of May, 1876, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Wednesday, the
seventh day of June, 1876, to pay the delinquent assess-
ment, together with costs of advertising and expenses of
sale. By order of the Board of Directors,
W. TRAYLOR, Secretary, pro tem.
Office, room 37, Nevada block, No. 309 Montgomery street,
San Francisco, Cal.

The California Watch Company—Loca-
tion of principal place of business, No. 120 Sutter
street, San Francisco, Cal.

Notice.—There are delinquent upon the following
described stock, on account of assessment levied on
the eighth day of March, 1876, the several amounts set
opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
M Oodley, trustee.....	1	3,000	\$15,000 00
A Rammelsberg, trustee..	2	200	1,000 00
A Rammelsberg, trustee..	3	100	500 00
T M Antieil.....	4	10	50 00
A Rammelsberg, trustee..	6	1,130	5,650 00
Paul Cornell.....	13	10	50 00

And in accordance with law, and an order of the
Board of Directors made on the eighth day of March,
1876, so many shares of each parcel of such stock as
may be necessary, will be sold at public auction at the
office of the company, on the first day of May, 1876,
at the hour of twelve o'clock, m., of said day, to pay
said delinquent assessment thereon, together with costs
of advertising and expenses of sale.

H. T. GRAVES, Secretary.
Office, No. 120 Sutter street, room 10, San Francisco,
Cal.

POSTPONEMENT.—By order of the Board of Direc-
tors of the California Watch Company, the above sale
is hereby postponed until Monday, the eighth day of
May, 1876, at the same hour and place as above set
forth.
H. T. GRAVES, Secretary.
San Francisco, April 26th, 1876.

Notice.—There are delinquent upon the following
described stock, on account of assessment levied on the
second day of March, 1876, the several amounts set
opposite the names of the respective shareholders, as
follows:

Names.	No. Certificate.	No. Shares.	Amount.
E A Richardson, trustee....	44	500	\$1500 00

And in accordance with law, and an order of the
Board of Directors, made on the second day of March,
1876, so many shares of each parcel of said stock as
may be necessary, will be sold at public auction, at the
office of the company, room 8, No. 315 California
street, San Francisco, Cal., on Tuesday, the second day
of May, 1876, at the hour of one o'clock, p. m., of said
day, to pay said delinquent assessments thereon, to-
gether with costs of advertising and expenses of the
sale.

J. F. NESMITH, Secretary.
Office, room 8, 315 California street, San Francisco,
Cal.

Lady Franklin Gold and Silver Mining
Company. Principal place of business, City and County
of San Francisco, State of California. Location of
works, Silver Mountain Mining District, Alpine County,
California.

Notice is hereby given, that at a meeting of the Board of
Directors held on the third day of April, 1876, an assess-
ment of fifty (50) cents per share was levied upon the
capital stock of the corporation, payable immediately, in
United States gold coin, to the Secretary, at his office,
507 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the 15th day of May, 1876, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Monday, the fifth day
of June, 1876, to pay the delinquent assessment, together
with costs of advertising and expenses of sale.

F. E. LUTY, Secretary.
Office, 507 Montgomery street, San Francisco, Cal.

**Peytona Gold and Silver Mining Com-
pany.** Location of works, Virginia District, Nevada.
Location of principal place of business, San Fran-
cisco, Cal.

Notice.—There are delinquent upon the following
described stock, on account of assessment, levied on
the 25th day of March, 1876, the several amounts set
opposite the names of the respective shareholders, as
follows:

Names.	No. Certificate.	No. Shares.	Amount.

T J Owens.....	7	40,000	4000 00

And in accordance with law, and an order of the
Board of Directors, made on the 25th day of March,
1876, so many shares of each parcel of said stock as
may be necessary, will be sold at public auction, at
the office of the company, room 5, No. 215 Sansome
street, San Francisco, Cal., on the 13th day of May,
1876, at the hour of one o'clock p. m., of said day, to
pay said delinquent assessment thereon, together with
costs of advertising and expenses of sale.

T. J. OWENS, Secretary.
Office, Room 5, No. 215 Sansome street, San Fran-
cisco, Cal.

To Mining Secretaries.

An amendment to Section 335 of the California Code,
taking effect July 1st, 1874, provides that in ad-
dition to the regular publication, daily or weekly,
of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation
from the law:

"The notice must be personally served upon each
stockholder, or in lieu of personal service, must
be sent through the mail, addressed to each stock-
holder at his place of residence, if known, and if
not known, at the place where the principal office
of the Corporation is situated."

NOTICE.

A Quartz Mine and Mill For Sale.

The Mill containing one five stamp battery, free
water power. Sample of rock from the Mine can be
seen at the MINING AND SCIENTIFIC PRESS office, San
Francisco. Location: Oregon Gulch, near Oroville,
Butte county, Cal.

About thirty or forty tons of Quartz are already out
and every day are taking out more.

A. GRUMMET.

SUTTER CREEK, February 26th, 1875.

MESSES. DEWEY & Co.—I have received my Letter,
Patent through your Agency. nd, for your prompt
ness, accept my thanks. Yours,
S. N. KNIGHT.

Natural History of the Seal.

At the meeting of the Academy of Sciences held on Monday evening last, Capt. C. Bryant, Government agent on the islands where alone the fur seal is obtained on any spot of territory under the jurisdiction of the United States, gave a statement of the sealery, and the habits of the animal toward which so many ladies of this State and the rest of the world have reason to feel under obligations. The sealery has been leased for 20 years to the Alaska commercial company, of which period seven years have expired. For this privilege the company pays the Government \$3.17 per skin, and being limited to 100,000 skins annually, the revenue accruing to the Government is \$317,000, or just sufficient to pay a small interest on the Federal investment in Alaska. Only the males are killed, and as this seal is polygamous, there is no danger of the species being exterminated. They are killed at their third year, when the fur is in the best condition, and just before they attain puberty, a condition of their existence which marks a deterioration of the fur.

The Males Reach the Islands

About the 10th of April, and are rarely more than four or five days behind time. The first of the females arrive on the 15th of June, and they give birth to their young from 10 to 24 hours after landing. All the females have landed by the 25th of July. The seals remain on the islands four months, eating no food during the whole time, and gradually getting thinner. Then they go away with the young, the males separately and the females separately, and where they go to is a problem. They go eastward and southward, and in the same way return. Nothing is known of their habits after leaving the islands. A strict herd or family relation is maintained, and the members of one family do not invade the domain of another family. The numbers are prodigious. A calculation in 1869 gave 1,130,000 females; the same method of calculation last summer gave 1,800,000, or an increase of five per cent.; 45 days old the pups begin to swim, four months old they can take care of themselves. Why the fur seal confines itself to these islands is probably due to the peculiarly favorable climate, not existing anywhere else on the North Pacific American territory. Twenty years ago

The Seals Got Scared

By too much killing and interference, and were gone three years. They did not all return. The absentees founded a colony near the Kamshatka shore, on the islands of Behring and Copper, and now their numbers amount to about one third of those on the Priveloff group. The mode of killing the three-year-old males with clubs is by driving them off in herds and allowing the older and younger ones to escape; the mode of skinning the carcasses and curing the skins, an account of the Aleuts who inhabit the islands, the strict care taken not to exceed the annual allowance of 100,000 skins, even for the sake of food to the natives—all this was dealt with carefully in the latter portion of the lecture. A few questions were answered, and a vote of thanks was passed to Captain Bryant.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

BEFORE PAINTING YOUR HOUSES

Send for Sample Card and Circular and Carefully Examine the

AVERILL CHEMICAL PAINT, MIXED READY FOR USE.

This Paint is prepared in liquid form, READY FOR THE BRUSH. It requires no addition of oil or spirits. It is composed of the best materials known to the trade—Pure Linseed Oil, Strictly Pure White Lead, Pure Zinc, and the finest of coloring matter for tinting. It is the BEST, CHEAPEST, MOST DURABLE AND BEAUTIFUL PAINT IN THE WORLD. Is just what is wanted by every farmer, mechanic and everybody who has a house, fence, barn, or wagon to paint. Requires no skilled labor, as any one can apply it who can handle a brush. It is put up in cans of any required size, from a quart to five gallons, and is sold by THE GALLON. It gives a firm, elastic and brilliant glossy finish, and will neither crack, peel or wash off, like most paint in common use, but is proof against rainstorms and all action of the elements. Buildings painted with this paint five years ago look fresh and like new to-day and will need no more paint for years. Of no other paint can this be said and proved.

The Averill Chemical Paint Company supply a long-felt want. They not only furnish a Paint more lasting, handsomer, and at the same time cheaper than the best of others, but it is in a liquid form—white and all the fashionable and most exquisite shades—ready for the brush. So that farmers, in fact everybody, can be their own painter if necessary. Indeed, all the buildings upon which the Averill Chemical Paint has been applied, are marvels of beauty.—*Christian Union.*

We know of no subject of such importance to householders as that of a good, handsome, durable paint for their dwellings. Within the past few years we have watched the progress of the Averill Chemical Paint and have had frequent opportunities to test it fully. We think it just the article to supply the need, and give it our hearty endorsement.—*N. Y. Independent.*

From the Thousands of Testimonials sent us, we select the following, which we present for your careful consideration:

A PAINT FOR FARMERS.—Prof. J. D. Turner, Jacksonville, Ill., is a man of great practical knowledge and experience; hence, we attach a great deal of value to the following, from his pen, which we find in the *Prairie Farmer*:

"Some two years ago I sent for and got from a barrel to a harrel and a half of Averill Chemical Paint, of light dun color, which I thought would suit me well enough for all work—houses, doors, blinds, fences, bee-hives, wagons, tools and all. I put two coats upon my residence here, and run over three or four of my smaller farm houses on my farms. With what was left I painted my bee-hives, wagons, wheelbarrows, rollers, harrows, fences, etc., etc., and on all these buildings, implements, tools, gates, etc., the paint is as hard and glossy to-day, as far as I can see, as it was a month after it was put on, and holds its own at least for five years to come, (if not ten of them,) better than ordinary white lead and oil does for even two years.

"I have watched it now for about two years with interest and care, and have never found a single spot where it peeled, cracked, or chalked off, as our other paints do. Others who have used this paint like it equally as well. But the point is, I can take one and the same key and brush, and go over all my buildings, wagons and tools, with no needless waste of paint, brushes or time. It is quite as good for inside finish, as it leaves a coat that shines and washes like glass."—*Moore's Rural New Yorker.*

THE AVERILL PAINTS.—In reply to some inquiries of our readers, we would state that we have given three paints, prepared by the Averill Chemical Paint Company, a full trial, and they appear to possess all that is claimed for them; spreading easily, adhering well, drying soon, and imparting handsome shades of color to the surface covered. Farmers and others who do their own painting, may avail themselves of the convenience of purchasing these paints, of any desired shade, already mixed for use, at a very reasonable price.—*Cultivator and Country Gentleman.*

PLACERVILLE, October 7, 1875.
To THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your letter I have to state that for more than six years I have dealt in and used your paint. I have during that time carefully observed its application and use, and from practical knowledge can certify to its unrivalled excellence. During my six years' acquaintance with it, there has not come to my knowledge a single instance of failure in any case where it has been used. All to whom I have supplied it unite in commending it for its superior claims over all other paints now in use. The Averill Paint externally used, or, in other words, exposed to the action of the weather, neither runs off nor changes color, as do other paints, and will retain its freshness and adhesive property for years. Pure lead and oil will in a short time become dry, and are easily rubbed off; the loss of oil leaves the lead in a dry, oxidized state. As a matter of economy the claims of the Averill Chemical Paint to popular appreciation and general use are beyond question. A house properly painted with it once will be better preserved, and present a neater appearance at the expiration of seven years, than it would if twice coated with lead and oil paints now in use. There can be no question, then, that to use it is both labor-saving and economical. So well assured and convinced am I of its established right to this distinction over all kinds, that had I fifty houses of my own to be painted, the "Averill" alone should be my choice and used.
Yours, very truly,
S. J. ALLEN, Druggist.

UNIVERSITY OF CALIFORNIA, BERKELEY, August 16, 1875.
To THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your note of the 13th inst., I willingly state that the work done by you in painting the exterior of the North Hall or College of Letters is in every way satisfactory, and the appearance of the building since it was painted excites the favorable comment of all who have seen it. As I have had occasion to use the Averill Paint before, my experience has been such that I prefer it to any and all others when properly applied. I am very truly yours,
ROBT. E. C. STEARNS.

ANGELL'S CHARCOAL DENTAL SOAP for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco.

HERCULES POWDER.

HERCULES Slaying the Giants.

[Hercules, the son of Jupiter and Alcmene, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Eurystheus to execute a very great task, when he found himself opposed by several Giants among whom were the powerful Giant Geryon, Eurytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.
2. **UNIFORMITY.**—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.
3. **SAFETY.**—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.
4. **CARTRIDGES.**—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.
5. **ECONOMY.**—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. {Hercules X X No. 1, for extreme hard rock.
Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself*:

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D., 1875.

Present:—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.
THE CALIFORNIA POWDER WORKS, *Ex AL.*, *In Equity*, No. 1,233—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., Solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered herein dismissing said bill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

October 18th, 1875.

SAN FRANCISCO, SATURDAY, MAY 6, 1876.

VOLUME XXXII
Number 19.

Crushing and Amalgamating Machinery of the Fryer Process.

In accordance with our promise in our issue of January 29th, we present our readers with a description and cut of the system of pulverization and amalgamation as practiced at the Fryer Works.

While we are not willing to indorse the Fryer process without a thorough knowledge of its operation, we open our columns to its managers to give our readers farther information by the accompanying engraving and description. We are informed that their works at Grass Valley are now open to public inspection.

As with our description of the furnace, published in the SCIENTIFIC PRESS of January 29th, we will give almost the exact language of the specifications, which cannot well be improved.

This invention relates to means by which ores containing gold and silver, in a free state, can be pulverized without amalgamation, or amalgamated after pulverization; or, at the same time and by one operation, be both pulverized and amalgamated.

Single Chamber.

A chamber is arranged to rotate, revolve, or oscillate upon or about a horizontal axis, and a weight or ram so placed within the said chamber that by the rotation, revolution or oscillation of the said chamber, the weight or ram will be caused by gravitation to have a reciprocating motion, falling from one end of the said chamber to the opposite end thereof. This weight or ram may operate to produce pulverization, or amalgamation, or both; after the ore has been placed within the said chamber, by falling upon the ore at the opposite ends of the said chamber, or by subjecting the ore to attrition between the weight or ram itself and the sides of the chamber.

Radial Chambers.

There may be a series of chambers around a transverse axis, about which they move, and a series of weights or rams arranged to reciprocate by gravitation within the said chambers, operating essentially as in the single chamber above described. Such combination of a series of chambers and their contained weights or rams moving around or about a common axis enlarges the working capacity of the apparatus, without inconveniently adding to its bulk, or to the space required for its operation. These radial chambers may be set either on a conical block, as represented in the cut, or on an octagon. These may be duplicated or the shaft as far as convenient.

Combination Chambers.

There may also be a centrally arranged separate amalgamating chamber, from which radiate a series of pulverizing chambers, with contained weights or rams, the said chambers moving about or around a transverse axis, common to them all.

By these means ores may be pulverized or amalgamated without loss of ore or metal contained therein during such treatment.

Having thus given the objects and nature of this invention, its construction will be more readily understood by reference to the accompanying engravings.

Single Chamber.

Fig. 2. A, working chamber, closed by ends or heads, C C, and supported and traveling upon trunnions, b b, to one of which prolonged is attached a gear wheel driven by a pinion. D' D', longitudinal bolts binding together the heads, C C. G, door or stopper, secured by cotter bar, f, and stirrups, g g, and rack wheel. E, weight or ram, which by its own gravity reciprocates from C to C as the chamber moves. For charges of about 250 pounds of ore A is about 5 feet by 20 inches, and revolves about 10, E then weighing about 230 pounds.

Radial Chambers.

Fig. 1. A represents a series of chambers, each with its containing weight or ram, E. In this plan, E slides upon guide bars D, and is of different shape from Fig. 1. Either or other forms of E can be used as circumstances require. G, doors or openings as in Fig. 1, c,

wheel, and d, pinion, by which power is applied. When it is desired to pulverize and amalgamate separately, the chambers, A, may be used for the former, whence the pulp may be admitted through the valves or doors, G' G', into the separate amalgamating chamber, I, to which, h h, are discharge doors or valves.

When using either form of chamber the ore is introduced through G in pieces of from brick

Don't Wait.

EDITORS PRESS:—You promised us long since that you would give us the full particulars of the Fryer process. We have waited and become impatient. We must have a mill of some kind. If Mr. Fryer has not completed his process so as to bring it out for sale, we will be

FIG. 1. THE FRYER PROCESS—CRUSHING AND AMALGAMATING CHAMBERS.

size downward, with a proportionate quantity of warm water, quicksilver and necessary chemicals, and then the apparatus is set in motion. The weight or ram, E, reduces the ore both by percussion and attrition. When the

compelled to try some other process. The gold in our quartz is fine, and we fear we cannot save it on the old fashioned stamp mill. We have no base metals to contend with.

We would say that any information in regard to the best process for working quartz and saving fine gold would be of importance to us.

H. C. COBY,

Etna, Siskiyou County, Cal., April 21st.

[If you have ore which will pay by any well known method, our advice would be not to wait for any new process. If you make your rock pay by an ordinary process, whenever a superior one is proven will be the best time for you to adopt it. We do not believe that even Mr. Fryer himself has advised any one to delay their work for his process.—EDS. PRESS.]

SELF-BLASTING ROCK—A STRANGE PHENOMENON.—The following curious statement is an extract from a letter dated "San Dimas, near Salinas, March 15th, 1876." The locality referred to is the Candelaria tunnel, of the Durango mining company: "At present there is on the 'Obra' one of the most singular effects manifesting itself that I ever heard of—the rock shoots or blasts of itself. It is very hard and solid, and will suddenly break with a noise much louder than a powder blast, and pieces fly with great force from 12 to 15 feet, as much as five or six tons having fallen at a single blast. Last week I had to stop work and timber, as one of the men was hurt by a 'natural blast,' and the rest refused to work. I want you to understand that these blasts are entirely different from 'caves,' the solid rock suddenly springing out from the face with a noise louder than that of a blast, and a force sufficient to hurt a man. They say that the same occurred at Tomlin, just before they struck the great bonanza. A. V. T."

JUNIOR McKEE has decided the laundry ordinance to be unjust and unreasonable.

The Silver Question.

[By ALMARIN B. PAUL.]

Well, Mr. Jones has finally delivered his silver speech, all of which is pointedly boiled down by the New York Times into "Buy my Silver." For so long a speech on so heavy a subject, it falls very light and adds but little, if any, to Mr. Jones' reputation as a political economist or statesman. To go into an analysis of this speech, and to combat his position for a double standard, would occupy more time than I have to spare, at present at least; and now comes forth Mr. Sharon, who makes (so the telegraph says) the important discovery that our government bonds do not say gold coin, but simply coin, "and this may have some weight" in carrying the double standard measures through. What is the inference? that our bonds can be paid in silver! When we take into consideration the fact that Germany is the largest holder of our bonds—that Germany nobly came forward, during our war, and backed us up with her gold; and in view, too, of her considering the demonetization of silver, it should be beneath the dignity of the United States Senate to hint at such an idea as the paying of our bonds in silver.

If better reasoning and propositions cannot be adduced for relieving the silver market, it will have to stand its discomfit. The fact is, our statesmen have got to look in a new quarter on the silver question before any relief comes of a permanent character.

All the intellectual stamina in the U. S. Senate cannot devise any law to force it where it is not wanted, excepting upon ourselves, and to force it upon ourselves is exactly what Europe would like to see, as then their silver would come in, and our gold by it be drawn out.

What we, as a silver producing country, have got to do, or rather should do, is to turn our minds towards India, study her trade and commerce, and through this channel pass off our surplus silver. India, in the past 26 years, has absorbed, of European silver, over \$1,000,000,000, and could take yearly more than the Pacific coast could produce. That more attention has not been given to the Indian commerce and exchange by our statesmen, commercial men and bankers is somewhat surprising.

With heads broad enough to grasp her trade, with the silver wealth which she covets at our hand, San Francisco, in a score of years, might make London fear the loss of the richest gem of her commercial crown; but alas, stock gambling is the grand idea of our millionaires, and the Cliff house the furthest their minds can range westward.

It must be evident that we have got to figure on the disposition of our silver outside of ourselves. To legislate it upon ourselves is but damming up the waters to overflow and engulf us by the loss of our gold; and what country offers so fine a field as the country which wants it, India? Knowing the product as I know it—knowing, too, how vast is the silver domain, and the great strides for its cheap production, I see the commercial world in less than a quarter of a century loaded up with it, and in such quantities unknown before in the world's history.

Well may Europe be exercised upon the subject, for they see the coming deluge. It is a question which is to puzzle the wisest. As before stated, with heads broad enough to grapple the Indian trade, San Francisco could be, with our silver, the queen of the commercial world—revel in effulgent splendor in this coming glittering age. Glittering age, do I say? Yes, through the light of statistics of the precious metals, I see the era close at hand which may well be termed the glittering age.

A GOON INEA.—A manufacturer of Springfield, Massachusetts, proposes to give young men and boys an opportunity to learn a trade by fitting a room with wood working machinery, benches, tools, etc., to be rented to those desiring to use them at a nominal charge of about one dollar a week, or fifty dollars a year and to furnish a competent overseer. He thinks that a boy could soon learn to make articles that would pay for his instruction, and he could learn mechanical drawing and practice with tools while in regular attendance at a day school.

Placer County Gravel Mines.

A correspondent of the Placer Argus is writing a series of articles on the mining interest, the last letter being from Iowa Hill. We extract the following information concerning that locality known as Bird's flat:

The Golden Gate, or Bowley & Jones.

This claim contains about 155 acres, most of which, large as it is, carries good hydraulic ground. It was first located in 1853, and drifted off and on nearly twenty years, paying enormously all the time. It was piped last year under the smallest rig, outside the rim, merely as a prospect, paying water money and wages; could be fixed up in first-class style for about \$4,000, giving 500 feet pressure, with all the water wanted. It would then employ eight men day and night for nearly a century at this biggest pay. Valued at \$10,000.

Medical Point, or Jones.

This claim contains about ten acres. It was piped from the beginning, and paid very well for the work done and the deficiency of power under which it was washed; in fact, the amount of ground worked under competent power, could be done in twelve days, yet it paid \$2,500. All this flat therefore, judging from actual developments, under proper appliances may be put down safely at from \$150 to \$200 a day. About \$1,000 would fix this claim up properly, and it would employ three men day and night seven years, supposing the pay not to run farther back than now expected. Valued at \$1,500.

In order to understand the extent of the present

Wealth of this Flat.

And the stretch of country from there to Wisconsin Hill, two miles south, throughout which the sniferous deposit is supposed to extend half a mile, or a mile, back from the canon into the hills, it is necessary to give my reasons for believing in that extent of rich gravel, as it has been doubted, perhaps is still, by men whose experience and knowledge I admit. In this stretch of country lie our best and largest claims, and yesterday's enormous clean-up of the Morning Star, located in the center, renders the question very interesting so far as the permanency of the splendid results of this season is concerned. Is it then, throughout the limits as it was on the present American river below from Rattlesnake Bar to Folsom, defined simply as a rim-rock deposit or a bark deposit of rich, reliable gravel in the basins behind? On the settlement of this question much of our future depends, and I therefore desire to avoid all exaggerated or deceptive ideas. For my own part I have always opposed the rim-rock theory, resting my opposition on science and practical experience. The gold found along the rim on the south side of Indian canon within the limits defined gives pretty strong evidence of belonging to the same rich lead found all through Menona flat, the base of Roach hill on the north side. If, as generally admitted, it is the same lead, then the configuration of the district would force it throughout Bird's flat in its passage south to the very base of the hills, though some of the claims at the extreme upper end may find themselves pinched in the extent of their pay dirt hereafter. Then, again, the lower section of the American river and the one in our neighborhood are distinct and separate formations, having no natural connection whatever; in fact, they were formed at different times and by different agencies. No one, accustomed to these investigations, will deny that the formation here is a part of that great pre-historic river, originally intersecting the entire northern portion of the State; a river of infinitely greater dimensions than anything known at present; or, that before Sugar Loaf gave way, and howed its once lofty head to its present limits, our auriferous territory was the bed of an immense lake, through which the river passed in its southern course to Yankee Jim's and Dardanelles by Georgetown, east of Centerville to Coloma, Placerville, Mokelumne Hill, down to the north of San Andreas gulch, 40 miles above Stockton, where it emptied into the great inland sea in a great measure contributed to form, and which was finally drained by the opening of the Golden Gate. Hence, the advocates of the rim-rock theory give no support in instantancing Whiskey, Dotens, Oondemned, Besle's Bars and Carrollton, where it was all rim-rock deposit, with Iowa Hill and vicinity, because the former are out of the passage of the great stream and belong to an entirely different period and agency. Besides, there is another theory in favor of our having a thoroughly auriferous gravel bed, which, individually, I strongly indorse. It is pretty well settled by geologists now, that rim-rock deposits are no evidence whatever of auriferous or non-auriferous gravel in the basins behind the ore, gold being deposited in the crust of the earth during the heated period of creation, while the igneous rock was soft; the others deposited through the gravel at subsequent periods by the eccentric action of water. This theory at once explains whatever was mysterious in our early California experience in finding heavy coarse gold in decomposed bedrock hundreds of feet below its present covering of gravel, and equally on finding a large extent of rich gravel above a barren bedrock. Evidently the two have no connection in natural law, and none, therefore, as they exist at Iowa Hill. But putting aside all scientific dicta, and turning to daily developments by practical experience, that great destroyer of human doubt and prejudice, do we not find everything tending to

establish the marvellous extent and richness of our hydraulic gravel range? Here are three of those developments: A fortnight ago, in washing gravel far enough back from the rim to test the question I am arguing, Dr. Kruse, at one end, washed up \$3,000 for a 20 days' run; the Swiss Boys, near the opposite end, \$3,500 for 13 days' run, and yesterday afternoon the Morning Star in the center, according to public report, about \$10,000 for 15 days' run. What more need I say? Nothing, except that according to actual experience this year, whether on the rim or off, if under the same splendid power used by these three companies, most of the claims on the entire range would run up the sum of pay the season through from \$150 to \$700 per day. So much for the rim-rock men who are conscientious in their judgment, and so much for the poor deluded ones below, who are not rational in their determination to see nothing but quartz worth investing in.

The tract of territory now spoken of, from Bird's Flat to Wisconsin Hill.

Besee no particular name, except that each point is known by the location upon it. Thus we come next to the Anstin. This claim contains 20 acres. It has been piped from this beginning, under 150 feet pressure and 200 inches of water, not sufficient to do first-class work, yet it paid two men good wages all through. At the cost of about \$800 it might be made to pay \$15 or even \$20 a day to the hand. The peculiarity of this claim is that it largely carries coarse quartz gold, very rough. A fine specimen, weighing nearly two ounces, and containing about \$20 in gold was found the other day, yet there is no evidence of a quartz vein in the district. The question then comes, could another ancient stream have joined the main river here from the neighborhood of Green valley, eight miles above, where I know there is quartz? Properly fixed up this claim would employ three men seven years. Valued at \$3,000.

The Swiss.

This claim contains 80 acres. It was drifted in early times and yielded largely, one piece of pure gold weighing about twelve pounds being found. For the last six years it has been under the pipe, well fixed up at a cost of \$4,000, with 200 feet pressure and 200 inches of water, and paid in that time about \$40,000. The last clean-up, three weeks ago, amounted to \$3,300 for 13 days' run. Employ's three men by day only, but if put under the power it admits would employ four men day and night for 20 years. Valued at \$15,000.

The Morning Star

Contains 160 acres under U. S. Patent. As the principal owners do not reside here I shall say but little about it. It is an old drift claim of reputation, with an immense bank of gravel, put under the pipe this season at a total cost of \$20,000. It has realized expectations, and proved itself the crack claim of the county. If not one of the banner claims of the State. As I have already said the clean-up on Saturday, according to public report, amounted to something like \$10,000 for 15 days' run. Its power is 500 feet pressure, with 1,000 inches of water. At present it is impossible to put any value upon it. In fact, it speaks for itself and the district too.

The Occident or Kidder Claim.

Contains 150 or 200 acres, of which 75 are known to be good hydraulic ground. Lying as it does between the Morning Star on one side and the De Kruse claim on the other, it may be considered in every respect, especially in its fitting up and arrangement, the second best claim in the district. It runs two monitors, with 400 feet pressure and 650 inches of water, 115 boxes on the flume and four under-currents. The last clean-up immediately after the sad accident to the late Mr. Kidder, as near as I can hear, was over \$4,000 for 23 days' run. I estimate the present run at over \$6,000. Total cost of fixing up \$5,000. It now employs nine men for day and night, and will last many years. This is one of the five claims that have settled the rim-rock question. Valued at from \$25,000 to \$30,000.

The De Kruse Claim

Contains 25 acres. It was prospected by shaft in early times, and put under the pipe in 1870, since which time it has paid very largely, excepting last season when there was such a sad want of water. This season it has averaged about \$3,000 to the run. It is worked under 300 feet pressure and 200 inches of water, with 800 feet of flume and three under-currents, the entire fitting up costing about \$4,000. It employs ten men at present, but averages eight for day and night. It will last for years, and is valued at \$20,000.

J. W. SLEEPER & Co., of Connor Creek mines, Baker county, Oregon, recently struck a very rich body of ore. It is stated that in quality and quantity it excels anything heretofore struck in that famous mine. The ledge is eight feet wide, and the ore is taken from a depth of 300 feet. Of this body of ore three feet in width fairly sparkles with gold, and the balance of the ledge is good milling rock, which will run from \$15 to \$20 per ton. The mine is very easily worked, very little blasting being required. Rock can be taken out and milled at a cost of \$7 per ton, including the wear and tear of machinery. In a run of three days (five stamps), Mr. Sleeper cleaned up 70 ounces, which in bar was \$44 fine, gold.

The mines in Southern Nevada are reported as more promising than ever.

Mariposa Land and Mining Company.

We have received, says the Mariposa Gazette, a pamphlet of twenty-one pages, giving a statement of the affairs of this company, which we find to be exceedingly interesting, even to those who have no personal interest in this grand estate. Heretofore the mines upon it have been worked for what was in sight, without regard to system or science. The \$12,000,000 gold bullion taken from them during the past ten or twelve years is less than the yearly product will be under the improved and comprehensive plan by which it is now proposed to work the most promising of them.

A personal examination and survey of the main central belt of veins on the Mariposa estate establishes beyond controversy that they are a part of the far-famed mother lode of California. They first appear on Mount Bullion, a short distance south of the Merced river, and run thence easterly from section eight to twenty. They are known as the Second Specimen mine, the Coin Specimen, the Queen, the Crown Point, the Linde, the Pine Tree, the Josephine and the Princeton. They have been worked to various depths, the ore producing from \$8 to \$60 per ton. A close examination shows that for many miles the ground is undisturbed, although the veins are plainly exposed and in some cases rise above the surface and run for long distances like great walls of white quartz. The cost of working the mines on this property has been so heavy, owing to the plan of mining by shafts, which require costly hoisting and pumping machinery, and where firewood is scarce and dear, that none but the richest ores can be worked to advantage. The experiment of erecting large mills on the Merced river to be run by water power was then tried, but an expensive road had to be cut, and as much hoisting and pumping was required as before.

In 1868, Mr. Mark Brumagin, after having thoroughly examined the estate, its resources and capabilities, and considered the problems of engineering, mining and reduction involved, recommended the water power of the Merced river as the basis of operation, by means of which all the mills could be driven and all the mining machinery kept running at nominal expense. Mr. Brumagin's plans were submitted to the company and adopted, and surveys entered upon for the route of a mining and drain tunnel, two and a half miles long. Work was commenced on this tunnel, and at the present time it is progressing successfully, at the rate of 100 feet a month, which will be increased by improved machinery 50 per cent. by the first of May.

The financial condition of the company is represented as good. Its expenditures for the past year have been large, owing to the settlement of liabilities incurred by the old company, in order to perfect the present company's title to the estate. These liabilities once extinguished, will reduce the expenditures to a few thousand dollars per month, as the greater part of the work is done by mechanical appliances, operated by water power and compressed air. In case the mills do not commence to run in two months, and a sufficient amount of bonds are not sold to meet this obligation, the company will resort to another assessment.

We are pleased to learn from this expose of the company's affairs that work of the most substantial character will be shortly commenced on the Princeton shaft, the engines and boilers having been already placed on the ground for the purpose.

We take pleasure in testifying to the vigor, energy and industry displayed by the present superintendent of this estate, Mr. E. C. Burr.

The pamphlet concludes with the following: "The diamond cross-cut, No. 3, having passed through a fissure vein 27 feet wide, carrying 10 feet in width of gold ore of low grade, which increases in richness as depth is gained, insures the success of the company's operations in this locality, and renders the early production of bullion a certainty. The point at which this large vein was intersected is opposite to the 1,400-foot station, and the main tunnel is at this time within 50 feet of that point. A working cross-cut will be run from the main tunnel to the vein, and ore will be taken out.

"The mills are being put in order as rapidly as circumstances will permit, and the additional machinery now building in the East is well nigh completed, and will be shipped by the first of May. It is therefore hoped and expected that everything will be completed so that the mills can be started by the first of June, if not earlier."

CALIFORNIA DIVIDENDS.—The Virginia Evening Chronicle, of April 22d, has the following speculations upon the ability of California to pay a dividend in May: "In view of the opening of the California mine and the crushing of 300 tons daily of rock averaging \$500 per ton, the sanguine ones considered it absolutely certain that there would be a dividend in May upon the results of the April production. They figured that 300 tons of this kind of rock would give \$150,000 per day, and a 30 days' run would give \$4,500,000; a \$2 dividend would require but \$1,080,000, and even if the unprecedented dividend of \$5 per share were paid it would amount to but \$2,700,000, which would leave for the reserve fund over \$1,000,000 after paying all expenses." The Chronicle then goes on to say that as the San Francisco papers reported a few days ago that no dividend would be paid until June next, a Chronicle reporter called at the Virginia office of the company and ascertained that no such plan had been definitely settled upon.

Darwin, Inyo County.

J. A. Acklin, who has been residing at Darwin during the past winter, returned here on Monday last. He kindly gives us, says the Kern County Courier, a few items of interest from that new and much talked of mining district of our "back country." Joe went to Darwin for the purpose of familiarizing himself in mining matters by practical experience, that he might, when brought in contact with mining men, know what they meant when they would speak of "dipe, spurs and singles, shafts, tunnels, stopes, cross-cuts, winzes, chimneys, true fissures, blowouts," etc. He represents himself as being well pleased with his sojourn in Darwin and as satisfied with the future mining prospects of Inyo county.

Of the several mining companies now in working shape and demonstrated as permanent mining enterprises about Darwin he mentions the Defiance, New Coso, Coso Consolidated, Cuervo and Dorgan companies. In Lee district, 10 miles north of Darwin, is the Emigrant company, with a consolidation of several good mines, and they are now erecting a mill and will soon be in operation, turning out high grade bullion. In Lookout district, 10 miles east of Darwin, the Modoc company have found an immense body of first class ore and will soon have a furnace or mill erected.

The Defiance company, in which some of our own citizens have interest, have been doing the most successful work during the past four months of the winter season. Since the first of January last they have erected their furnace and kept it running continuously, and, as a master of course, contributed largely to the bullion shipments from Inyo. The Defiance has had the good fortune to have fine grade smelting ores in every portion of the mine where they have wished to sink shafts and run tunnels and drifts and cross-cuts—paying their way in all of the "dead work" it has been necessary for them to do to put their mine in proper condition for successful mining. They are at this time putting up extensive hoisting works and will in a short time add another furnace to facilitate the reduction of ores. The management of the company has been by men who have not had "too much" experience in mining, and consequently it has been a success.

The ores of the mines belonging to the New Coso company have recently improved in quality, and success will wholly depend on the management. They have two classes of ore, one suited for smelting and the high grade for milling.

The Coso Consolidated company is developing a new and encouraging feature at this time, it having gone down somewhat during the early part of the winter, owing to "too much" experience on the part of its first manager. It is now under the management of a party who will bring it out all right.

The Cuervo company have a very large surface property and it is believed that the developments of the next few months will enable them to make astonishing revelations of mineral wealth.

The Modoc company recently run into a body of ore in which, to use the language of one of the miners, "they could see trade dollars without any discount." It is claimed to be the richest deposit of silver ore ever discovered on the coast, and they have not yet got through it.

The Emigrant company are opening up fine milling ore, and was considered "way up" until the Modoc put in an appearance as "chief." The Emigrant will have its mill in operation about the first of June.

The Dorgan company have not yet developed anything "bonanzaic," but everything is encouraging.

Of the town of Darwin, Joe says, it has had a quick growth, but is now comparatively quiet, though there is but little complaint among business men. There are a large number of miners employed by companies, and of course they are consumers of the necessities and go for the luxuries when they are to be had—which, Joe says, we are sorry to say, do not often turn up in that dry, barren country.

DANGER OF OLD SHAFTS.—A correspondent of the Placer Argus, writing from Iowa Hill, in speaking of the De Kruse claim says: I suppose it is not too late to tell you of a singular and unpleasant incident occurring in this claim about a week since. On piping away the bottom of an old shaft they found the skeleton of some poor fellow, with his blankets tied up in the usual traveling style. It seemed to have been in a standing position before struck by the water, one foot retaining the boot afterwards. The cloths appeared to have been of a respectable character and evidently but little worn. The remains are supposed to be those of a man who made a part payment for a claim here, and then went to Yankee Jim's to draw \$1,500 he had on deposit there, but was never heard of afterwards. What a horrible fate! Yet there are many of these villainous man-traps in our vicinity, left wide open, which if ever washed to the bottom may tell a similar story. Whose business is it to see that the more dangerous ones are covered over? Nobody's, I suppose. Human life, I know, is not of much value in this country, yet common Christianity suggests that somebody may be held responsible hereafter. Messrs. Supervisors and Road Masters, how do you feel on the subject? Are your consciences satisfied? Yes?—well then so is mine.

The Black Bear mine at Salmon river has taken out \$14,000 during the last four weeks. Last summer the yield was \$26,000 per month.

MECHANICAL PROGRESS

The Centennial Engine.

The Philadelphia Times gives some interesting facts concerning the starting of the mammoth Corliss engine which will furnish the power in "Machinery Hall."

The contract between the Centennial authorities and George H. Corliss, of Providence, R. I., obliged the latter to have his great engine in Machinery Hall completed and ready for action by yesterday, the 10th of April. The announcement circulating through the grounds that in the evening this gigantic source of the motive power that will operate upwards of a dozen acres of machinery would be set in motion for the first time, a great crowd of employees and others congregated about the iron giant before five o'clock. Steam had been created in four of the twenty boilers required to feed the engine, and was turned upon the latter half an hour later.

The engine weighs 800 tons; will drive eight miles of shafting; has a fly wheel 30 feet in diameter and weighing 70 tons; is of 1,400 horse-power, with a capacity of being forced to 2,500 horse-power; has two walking beams, weighing 22 tons each; two 40-inch cylinders, a 10-foot stroke, a crank shaft 19 inches in diameter and 12 feet in length; connecting rods 24 feet in length, and piston rods six and one-fourth inches in diameter. The platform upon which it rests is 55 feet in diameter and composed of polished iron plates, resting upon brick foundations that extend far down into the earth. The height from the floor to the top of the walking beams is 39 feet. Of the eight lines of shafting (four on each side of the transept) seven will have a speed of 120 revolutions per minute and one of 240.

At precisely half-past six o'clock the Director General raised his arm as a signal, Mr. Corliss patted his huge iron pet as if it were a frisky nag that he was coaxing to move, when a slight puffing was heard, not near so loud as that of a railway locomotive when about to start, one of the beams began to descend, and the fly wheel to turn, and the engine was in motion. Without waiting for more, every spectator took his hat in his hand and swung it in the air, the action being accompanied by a cheer so deafening that nothing could exceed it in enthusiasm except the cheers that followed it.

Everybody appeared to understand the significance of the moment, and the practical appreciation of it shown would be worthy of the opening day. The motion of the engine was astonishingly noiseless, nothing being heard above a uniform murmur, resembling the well known sound of a well set wheel in rapid revolution. There were but 14 pounds of steam generated by the four boilers, and the revolutions of the fly wheel at starting numbered 15 per minute. The shafting cog-wheels, portions of which rise above the floor in distant parts of the building, though revolving with great rapidity, were even more noiseless than their gigantic motor. It was long before the spectators could turn away from the grand sight, and when they did it was to speak in admiration of that power in man which can invent the means of accomplishing the power of many giants with none of the bustle made by one child.

A New Telegraphic Machine.

The New York Post describes a new telegraphic machine invented by J. B. Fuller, and now on exhibition in that city, as follows: It is worked not by the battery power, but by a small steam engine, and constructed to operate either the Edison automatic or the Morse system. By the Edison system, 1,500 words a minute have been sent 50 miles, 1,200 words a minute to Philadelphia, and 800 words a minute 800 miles. The defects inherent in the magneto-electric machines heretofore in general use are, first, that their electric waves are given off in short disconnected discharges; secondly, that in heavy storms their batteries sometimes refuse to work; and thirdly, that the force of machines large enough to operate hundreds of lines of various lengths cannot conveniently be so controlled as evenly to operate only a single line. In the Fuller machine these defects do not appear. It not only lengthens the waves, but also laps them one over another in such a manner as to produce one uniform continuous current. It in no degree sympathizes with immoderate rain, wind or snow. And it possesses self-control sufficient to send a message with equal ease and clearness over a short distance as over a long one—over a single line as over many lines. In order to augment the electric force of the machine it is necessary only to increase the number of the magnets and the motive power of the steam engine. A machine capable of working 50 lines of telegraph wires can be run by a Baxter engine of four horse power, consuming not more than six scuttles of coal a day; and it may be placed either in the operating office or, if more desirable, a score of miles away, where it can be run by the water power of a stream, instead of by steam power. Electricians and capitalists who have been watching experiments made during the last few months are much interested in the results. The apparatus will soon be removed to the Western Union telegraph building on Broadway, in order to operate the instruments of the Gold and Stock telegraph company, which are said to require the largest amount of battery power ever used anywhere.

A Novel Piece of Mechanism.

Mr. Andrew Gendron, of Detroit, is, after nearly a year of constant labor, about completing a complicated piece of mechanism intended to represent the "Resurrection of General Washington," and which it is his intention to exhibit at the Centennial exposition. The whole apparatus is inclosed in a cabinet nine feet high, three and one-half feet broad and two and one-half feet deep. The lower half contains the machinery, and in the upper portion the diorama is displayed. The scene is a facsimile of the tomb of Washington. Upon one side stands an American and on the other a French soldier of the present day, while at the side end upon the recess beyond are painted allegorical figures and emblems. The machinery, which is quite complicated, is operated by a spring similar to those used in a clock. When it is set in motion a miniature cannon is fired, a bell is tolled, and a curtain, suspended across the face of the recess of the cabinet, rises slowly, bringing to view the tomb and sentinel soldiers. The latter stand at "an order." In the course of a minute or two the tomb opens, and a facsimile of the Father of his Country arises therefrom. Simultaneously, the soldiers face toward the tomb and present arms, and Washington performs the usual military evolutions. Then there descends from the clouds an American eagle, holding in its talons a staff, on one end of which is an American flag, and upon the other the national emblem of France, carrying in its beak a laurel wreath, with which it crowns the resurrected Washington. The machinery continues to revolve, and the scene is reversed and repeated as often as desired, each representation requiring about three minutes. The figures are made upon a scale of about three inches to the foot. The heads are carved by Mr. Julius Melcher, and the bodies are minutely correct and properly proportioned. The guns carried by the soldiers are in exact imitation of Springfield rifles, and the costume of the soldiers is patterned after the uniforms of the armies of this country and France. The dress of Washington is the same in color and style as that worn by him at the battle of Trenton. The construction of this curious piece of mechanism has brought out a great deal of ingenuity, and, as can be readily surmised, embodies a great amount of fine skill and workmanship. —*Detroit Evening Bulletin.*

TASTE IN PAINTING MACHINERY.—The *Cabinet Maker* some time since published an article upon the gaudy manner in which machinery is too often painted; it is too often drenched with the most glaring and ill-contrasted colors, that disgust the sight and mar the appearance of the machine. The following remarks will assist our readers to a better comprehension of what we mean, and also to select proper artistic contrasts: We have seen machinery in which bright, gaudy reds and scarlets mingled with bright blues and yellows in the most extraordinary way. A very little consideration will show that such combinations are breaches of the laws of harmony, which require that one color shall be subservient to the other, so as to perfectly blend the whole to an even and pleasing tone. Thus, the complementaries of red are green; of blue, orange; of yellow, violet. Precise rules, however, cannot be laid down, and much depends upon artistic effect to be decided by the eye. The following suggestions as to contrasts, however, may be found of assistance: (1) Black and warm brown; (2) violet and pale green; (3) violet and light rose color; (4) deep blue and golden brown; (5) chocolate and bright blue; (6) deep red and gray; (7) maroon and warm green; (8) deep blue and pink; (9) chocolate and pea green; (10) maroon and deep blue; (11) claret and buff; (12) black and warm green; (13) slate color with nearly all bright colors, excepting blues; (14) buff and black; (15) buff and blue or mauve, and so on.

AMERICAN RAILWAY CONSTRUCTION.—During 1875 the greatest mileage in any one State of America was built in New York, 200 miles having been added. California came next with 174½ miles; Illinois third, with 172 miles; Pennsylvania fourth, with 118 miles; Colorado fifth, with 113½ miles; Indiana sixth, with 109½. In none of the other states was an aggregate of 100 miles reached. The following States and Territories built none: Alabama, Alaska, Arizona, Dakota, Florida, Idaho, Indian Territory, Kansas, Kentucky, Louisiana, Minnesota, Mississippi, Montana, New Mexico, Oregon, Rhode Island, Tennessee, Virginia, District of Columbia, West Virginia, and Wyoming. Comparing the figures (1,483 for 1875 with the 2,449 miles of 1867, 2,979 miles of 1868, 5,118 miles of 1869, 5,525 miles of 1870, and 7,779 miles in 1871, it is easy to see the effect of the panic and the subsequent hard times upon American progress in the development of internal transportation facilities, and also to understand how it is that the iron trade, at one time enormously stimulated to meet the requirements of railroad construction, now languishes because the consumption on account of new rails alone, to say nothing of equipment, is reduced to about one-fifth of that of 1872, and because, to supply this, the special industry of steel rail manufacture calls for special grades of pig metal.

A PHILADELPHIA firm has manufactured for exhibition a large cast iron chain of 38 links, to represent the 38 States.

SCIENTIFIC PROGRESS.

Coal Dust for Fuel.

We have made former mention of efforts to utilize coal dust as fuel. We now find in our exchanges for the week two interesting paragraphs claiming success in this direction. First we take from the Harrisburg (Pa.) *Chronicle*, the following:

The problem of the utilization of coal dust seems to be in a fair way of solution. The trouble has always been that it would not burn because it was too compact and would rather smolder than ignite. For 50 years that has been the one great impediment, and scientists could not overcome it. Finally, however, Superintendent Wooten, of the Reading railroad, thought of introducing a steam blast through the coal from the bottom, in the hope of penetrating the mass and supplying plenty of air. He built a furnace specially for it and placed it under a stationary engine boiler. Instead of using grate bars he employed a perforated iron plate for the fire to rest upon. A pipe from the boiler conveyed the steam end the necessary pressure supplied the blast, and this stroke proved to be the keynote of the entire dirt problem. It burned freely and threw out an immense heat. The oldest dirt was used to see if it possessed burning qualities, and it was found that it consumed freely, the same as the best of coal. It was next tried in the furnace of a locomotive engine and was found to burn equally well. The other day, when the wind was blowing at the velocity of 40 miles an hour, a coal dirt burning engine took up a train of 100 cars through the valley with the same ease and with as little labor as an engine burning the very best anthracite coal. This is regarded as a great revolution in the coal and iron country, because it transforms at least 1,000,000 tons of heretofore useless coal dirt into a fuel worth, at the very least, \$1 per ton, and provides a way to consume all coal dirt that may come to the surface in the future.

A Compressed Fuel.

The experiments of E. F. L'Oiseau have been mentioned previously. There are, however, new works and new machinery which are very interesting. The New York *Tribune* describes the new establishment at Port Richmond, Pa., as follows:

The new fuel is composed of 95 per cent. of coal dust and five per cent. of clay, with a small amount of a glue-like mixture made of rye flour and slaked lime. It is in pieces of the shape and size of hens' eggs. To make the pieces impervious to water they are dipped in a solution of "candle gum," a residuum of paraffine and crude benzine. All the manufacturing processes are novel and ingenious. The clay is dried in an oven on sheet iron plates, the fire being in an iron car running on a track, so that it can be pushed forward or backward under the plates. Then the clay is hoisted up to an upper story, pulverized in a mill and deposited in a wooden receptacle. Close at hand is an iron boiler, eight feet in diameter and eight feet high, in which the paste is cooked by steam and stirred by revolving paddles. The paste is of the consistency of thick cream and escapes by a pipe at the bottom of the churn. The coal dust is drawn up on an inclined plane in small cars and thrown upon an oscillating wire screen, which takes out all pieces of slate or small chunks of coal. As the dust falls through it is carried in an endless chain bucket elevator to a bin holding five tons. Now the dust and the clay fall down into a curious little machine that measures out just the proper proportion of each and throws both ingredients of the future fuel into a common receptacle. But while they are dropping into this receptacle they receive a sprinkling of the liquid paste from perforations in an iron pipe. Another chain elevator takes the commingled ingredients up and deposits them in a huge iron churn holding six tons, in which are seven revolving shafts that swing their great toothed arms about in opposite directions and thoroughly mix the black grist. The substance now is of the consistency of moist sand. It falls upon a leather band and is carried to the hopper of the pressing machine. This consists of two iron cylinders 30 inches in diameter and the necessary apparatus to revolve them. The cylinders are each indented with 870 large molds and 56 small ones, and as the molds on the two come together they press the soft mixture into shape and afterward drop the egg-like chunks upon a moving wire-cloth belt below. The larger pieces weigh 2½ ounces each and the smaller ones half an ounce. Thus far the operation has been wholly automatic, and so it continues to the end. The egg coals, as they might well be called, must now be dried. They are dropped upon another wire belt that carries them into a great oven heated to a temperature of 250 degrees, and fall successively upon still other belts traveling in opposite directions, until they have gone the length of the oven five times. When they come out they are ready for burning, but must be "water proofed" to protect them from dissolution if caught in a rain storm. For this purpose another traveling wire belt, across which there are upright partitions of wire, catches them and gives them a bath of two seconds in an iron tank containing a solution of candle gum and benzine. The tank is inclosed to prevent the escape of the fumes. From the tank the coals go to a big bin called the evaporator, which holds 15 tons. The benzine fumes rise

through pipes to a condensing coil and the recovered liquid is conducted back into the tank from which it ran into the bath. After remaining about an hour in the evaporator the coals fall upon another moving belt, which deposits them in the final receptacle—the "pocket"—from whence they roll into the coal carts.

From the time the clay went into the mill and the coal dust was emptied on the separating screen the material has traveled a distance of 743 feet without being once handled. In the succession of ingenious automatic processes lies the secret of cheap manufacture. The factory will produce 150 tons a day with one set of machinery, and the product will be sold for \$1 a ton less than the price of stove coal.

Subterranean Telegraphy.

In a communication to a Continental contemporary, Niemeyer, sub-director of the royal telegraph station of Amsterdam, observes that the disadvantages inherent in the overland telegraph lines are more or less known, their inefficiency under unfavorable meteorological influences, such as in foggy or stormy weather; then their possible destruction, by trains running over the line, or other mechanical causes; all these causes have tended to occasion interruptions in the transmission of telegrams, often at a time when velocity of transmission was urgently demanded. Although, he continues, the pernicious effect of meteorological influences working against the speedy transmission of telegrams had already received attention at the time when electric telegraphy was introduced, still the subterranean lines then had to be abandoned on account of their imperfect isolation and the overland method was adopted in their stead. Notwithstanding that improvements in the isolation of subterranean wires were being constantly applied with perfect success, owing to the cheapness of first cost and superior convenience for repairs, the system of overland wires has been generally preferred and been very largely developed of late years, with, however, the result of almost daily interruptions. The cost of maintenance and repairs becomes thus much enhanced, although, after all, the overland system is, even now, as expensive as the subterranean system. With special reference, however, to the uncertainty of telegraphic transmission, the overland telegraph certainly does not always fulfill its functions, consequently, at the establishment of a sure and speedy means of communication is what we desire to obtain with the telegraph, the cost of its construction ought to be of secondary importance when compared to its ultimate object. Now, with an improved subterranean system these annoying delays might be obviated. The credit of having first looked at the proper side of the question at issue and treated it with the attention due to its importance is claimed by the North German telegraph administration. Six years have elapsed since this was done, and the plan that was then proposed is now to be carried out in Germany, inasmuch as a subterranean line between Berlin and Halle on the Saale has been commenced.

A CHINESE SCIENTIFIC JOURNAL.—There lies before us, says the *Scientific American*, a very curious periodical. It is a pamphlet of about 30 pages, stitched with green silk in covers of the brightest yellow. On the back, or rather the front, for the book is read backwards, there is a strip of red pink paper, covered with hieroglyphics. The pages are each double, that is to say, instead of the print appearing on each side of the sheet, it is impressed on one side, the sheet is folded, and the free ends bound upwards, so that the edge of every leaf is a fold. The paper is of that soft India variety used here for engravers' first proofs. Finally, the characters are all Chinese and printed in vertical lines. Such is the appearance of the first Chinese scientific journal, the *Chinese Scientific Magazine*. The editor, Mr. John Fryer, tells us, in his prospectus, that the journal is to "serve as an introduction to the translation of scientific books already existing in Chinese; it will contain notes or lectures on scientific subjects," and in brief is intended to disseminate useful scientific and practical information throughout the country.

ELECTRICITY AS AN AID TO EGG HATCHING.—The *Oestrheinische Landwirtschaftliche Wochenblätter* states that Dr. Virson, superintendent of the Italian experimental silk farm, at Padua, has discovered that the hatching of silkworm eggs, of suitable age, may be accelerated by a period of 10 or 12 days, and a yield of at least 40 per cent. of silkworm caterpillars secured, by exposing the eggs to a current of negative electricity from a Holtz machine for a space of eight or 10 minutes. It is suggested that the same method might perhaps prove useful in promoting the hatching of hens' eggs and in hastening the germination of various seeds. —*Quarterly Journal of Science.*

JUPITER'S SPOTS.—Flammarion publishes some interesting observations of Jupiter, made in 1874 and 1875, and sums up his work substantially as follows: These observations fix the principal aspects of the planet during these periods of opposition. They show that the visible surface of this globe is very changeable, but that, nevertheless, some of the spots persist for entire weeks; that these spots are accompanied by shadows, diffuse and nebulous; that the shadows of the satellites are sometimes gray and sometimes black; and that the tints of different portions of the planet not only differ from each other, but change in tone and intensity from time to time.

Compositions of Ancient Style and Date.

Mr. Wm. S. Moses, of San Francisco, has furnished us the following primitive and quaint but "fair square" Centennial documents, executed, respectively, in 1769 and 1735, "the said" Ben and Tom Phelps being ancestors of our friend Moses, who proves his true Yankee type by various ingenious inventions, one of which is an improvement in tilting drawers, for which he has recently secured letters patent through the MINING AND SCIENTIFIC PRESS Patent Agency. Mr. Moses followed his father in wood working, but he informs us that their ancestors were blacksmiths. The enl mentioned in the SCIENTIFIC PRESS last week as being sent to the Centennial was "brought over" from England in 1733 by John Moses, the great-grandfather of William.

[NEED OF A MINERAL BEARING FARM.]

Know all men by these presents that I, Benjamin Phelps of Simsbury in the County of Hartford and Colony of Connecticut, for a valuable sum of money, viz. ten pounds lawful money to me in hand paid received by my full satisfaction of Thomas Phelps of Simsbury do hereby release and release and farm let unto him the said Thomas Phelps and to his heirs, assigns, for, and during the full term of nine hundred and ninety nine years next ensuing, the one half of all the mines, minerals, metates, and oars of metates of what nature, kind or quality whatsoever, that or shall at any time hereafter during said term be found in any part or parcels, of the lands which I have ever bought of him the said Thomas, in the bounds of Simsbury in the West Simsbury Society, with full liberty for him the said Thomas, his heirs or assigns, at any time, or times during said term, to enter upon the premises, to dig, search for, sink shafts, work and separate any such oars or metates and with teams and carriages to carry away, all such oar, or metates, and oars of metates and of the said shafts and to raise on said land, (only reserving to myself heirs & assigns at my own cost & labour, to carry on the one half of the business of raising oars, &c., as aforesaid for my & their own profit & use. To have and to hold the said released and released premises with the appurtenances thereof unto him the said Thomas Phelps his heirs & assigns with-out let suit claim hindrance or molestation from the said Benjamin Phelps my heirs executors or administrators, or any other person or persons from by or under me, in witness whereof I have hereunto set my hand and seal the 24th day of April, 1769.

Signed sealed and delivered in presence of JOSIAH CASE, ABRAHAM CASE.

[A "STERLING" BILL OF SALE.]

Windsor givly 22d 1735 then received thomas phelps of windsor the sum of three shillings money it being in full of all debts bills bonds or any other accounts whatsoever betwixt the sd phelps and allin from the beginning of the world to this day as witness my hand

ALEXA ALLIN.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

CONCORDIA G. & S. M. Co.—May 1st. Location: Virginia district, Nevada. Capital stock, \$15,000, in 150,000 shares of \$100. Directors—L. Lettewer, Wm. Hindoff, H. W. Jangeman, L. F. Holtz and A. Selbach. BRETHERTON G. & S. M. Co.—May 1st. Location: Virginia district. Capital stock, \$15,000, in 150,000 shares of \$100. Directors—L. Lettewer, Wm. Hindoff, H. W. Jangeman, L. F. Holtz and A. Selbach.

CALIFORNIA FURNITURE SPRING MFG. Co.—May 1st. Object: To manufacture and sell bed and furniture springs. Capital stock, \$50,000, in 500 shares of \$100 each. Directors—James Eaton, Amos S. Water, Wm. A. Crawford, C. B. Spalding and James English.

NEW ERA G. & S. M. Co.—May 3d. Location, Alpine county, California. Capital stock, \$10,000, in 100,000 shares of \$100 each. Directors—E. A. Hatherton, P. Amiraux, C. Wittman, W. A. Beal, E. F. Russell, G. W. Bowie and C. M. Grant.

SAN FRANCISCO AND CALIFORNIA M. Co.—May 3d. Location: Liguria, Chile. Capital stock, \$1,000,000, in 20,000 shares of \$50 each. Directors—W. B. Ewer, W. B. Quinby, W. H. Murray, A. H. Evans and Arthur P. Buros.

MOLLE STARK S. M. Co.—May 3d. Object: To mine and mill and to do a general mining business. Capital stock, \$10,000, in 100,000 shares of \$100 each. Directors—Wm. H. Gray, L. Van Schaick, H. P. Klus, A. F. Sturt and V. N. Putnam.

LAKNERCHUBB G. M. Co.—May 3d. Location: California. Capital stock, \$5,000,000, in 55,000 shares of \$100 each. Directors—J. James Laedrich, John C. Laedrich, Wm. Kulberg, Isaac B. Crocker and Nathaniel Hunter.

ANOTHER WIRE RAILROAD.—At the last session of the Board of Supervisors there was passed to print a grant of a franchise to construct the California Street wire cable railroad, to commence at Montgomery street and extend as far as First avenue. The movers of the project are Leland Stanford, Merck Hopkins, David Porter, Isaac Wormser, P. H. Canavan, E. B. Pond, Robert M. Graves, John H. Redington, Michael Reese, Louis Sloss, B. Adolph Becker, Charles Crocker, D. D. Colton and others. In the event of no unexpected obstacles being encountered, the promoters promise that work shall be commenced within six months, and the road completed within two years thereafter. All the owners of property along the route who have been consulted on the subject are claimed to be in favor of the project, and ready to contribute substantial aid.

A PARTY of Black hills miners just returned to Sioux City say there is no fodder for cattle or horses in that country, and that stock is dying off rapidly from starvation. The grass is not yet started, and in many places snow still covers the ground—to the depth of a foot in the vicinity of Custer City. This party counted the carcasses of four hundred animals that had recently died of disease and starvation.

ENWARRN BARNON has resigned as President of the Consolidated Virginia mining company, and C. H. Fish, formerly Secretary, has been elected to fill the vacancy. A. W. Havens has been appointed as Secretary.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR. TO BE STARTED UP.—Amador Ledger, April 27: It is rumored that the Mahoney mine, of Sutter Creek, will be started up at no distant date. The mine has been idle now for more than a year. Contradictory reports are about as to the quality and quantity of the ore-body met with in this property. It is claimed by many that the mine is a paying one, and that its suspension was a dodge on the part of some of the shareholders to get the property into their own hands. At any rate we hope to report of a speedy resumption of work may prove true. It is just what Sutter Creek needs at this juncture.

INCREASE OF STAMPS.—The Phoenix mining company of Plymouth have decided to increase the capacity of their mill by the addition of at least 20 stamps during the summer. The machinery of the mill is capable of running 60 at 40 stamps. The Phoenix is evidently entering upon a prosperous era. There is some talk of working the Alpine mine, which belongs to the same company, and adjoining the Phoenix works, by running drifts from the Phoenix. Plymouth is as lively a camp as there is in the county, and several buildings, we hear, are in course of construction.

THE GOVERN MINE.—Amador Dispatch, April 21: This mine, which is located near Amador City, and superintended by John Phelps, was last week still yielding handsomely. They make a "clean up" every two weeks, and the average yield is about \$9,000 per month, besides the sulphurates, which afford an additional yield of from \$2,000 to \$3,000 per month. The shaft is now down about 700 feet, and good paying rock is found in all parts of the mine.

THE YERDA MINE.—We are informed that the Onelid mine now taking out and crushing a very superior quality of rock. It is now running 40 stamps by water power, which it gets from the Amador canal.

CALAVERAS.

A BONANZA.—Colnverra Chronicle, April 29: We learn that rock of incredible richness continues to be taken from the Grasshopper mine at Mosquito. Parties who have visited this rich mine inform us that the ore being taken out absolutely glitters with free gold. It will yield thousands of dollars per ton. The ledge widens as operations progress, its average thickness at the present depth—100 feet—being 18 inches. There are about 15 tons of ore now in the dumps, and more is being daily added to it from the 100-ft south level, all of which is rich. When the Grasshopper ore is crushed, we expect to be able to chronicle the largest average yield per ton ever recorded in the State.

SINKING.—The work of sinking the San Bruno shaft, at Mosquito, has been commenced and good progress is being made. A strong force is employed.

COLUSA.

RICH BONANZA.—Colusa Independent, April 29: The Abbott quicksilver mine is turning out some of the finest ore that has ever been taken from the bowels of Mother Earth. The controlling interest in this valuable mine is owned by Jackson Hart and W. F. Goad, of this place. It seems that the faster the miners penetrate into the earth, the richer the ore becomes, and they will not have to go much farther, at present indications, to reach the pure metal. We have examined another specimen from the Abbott this week, that is as near pure quicksilver as ore can be expected to become. This specimen is about the size of a common brick, and weighs between 14 and 15 pounds. It is a beauty, and will go to the Colnverra or beyond of the ore men. The fortunate owners of this mine feel jubilant over their prospects.

EL DORADO.

RICH.—El Dorado Republican, April 27: We learn that A. J. H. is making a rich investment among the mountains of the old Jack Johnson meadow. He has already taken out several thousand dollars in beautiful coarse gold, and we are told by parties who ought to be able to judge, that if they had the claim they would not give ten cents to be insured \$50,000 for the season's work there.

INYO.

DEFIANCE MINE.—Inyo Mining News, April 29: Our trip to the gold ledges and Lookout last week precluded a report of this mine, which continues to improve with every day's development. By permission of P. Reddy, Esq., the superintendent, we made a visit to the mine on Wednesday, and through the courtesy of Mr. S. Hubbell, the very competent foreman, we inspected the latest developments. In the north surface workings the winze is down 30 feet, the ledge at this depth being 28 to 30 feet in width, with ore from top to bottom, although an occasional boulder is met with, but the ledge is well determined. In the raise from the main tunnel a magnificent body of ore has been encountered in the upper workings, and as the same body is found in the lower workings, there is no doubt but that it extends clear through. Since our last visit a drift has been started near the hoisting works, running northward, and is now in 75 feet. This drift is intended to strike the ore body north, which is immense. The winze from the main tunnel west, some 300 feet from the south, is now down 25 feet, all the way through ledge matter, with occasional bunches of good ore, the last indications and ledge matter raised therefrom showing that a large body of ore will be struck within a few feet. The two adopes from the south winze, running north, are looking splendidly, large amounts of fine ore being extracted. The other parts of the mine are in good shape. The hoisting works are all completed, and the work on the shaft will be commenced immediately. The boiler, engine and other machinery are now on the ground.

DEFIANCE FURNACE.—The leak in the water-jacket, of which we spoke last week, finally became so serious on Monday last that the furnace was shut down to await the arrival of the new jacket. It arrived yesterday, and Mr. Shepard, the furnace superintendent, is busily engaged in putting it in position.

VETERAN.—This mine was located by Captain D. B. Akey, and is the first extension of the Confince mine, belonging to the Modgo Consolidated mining company, and is being opened by a tunnel at the foot of the mountain at a point where the ore body has been encountered in being run in directly on the ledge which crosses the mountain at a right angle, the Confidence, Eclipse, Kentucky and Minietta claims being on the same ledge, which runs directly through the hill, as is seen by the hold croppings, which are traceable for at least 6,000 feet. The tunnel on the Veteran is in some 15 feet, is about seven feet in width, with ore on all its sides, and the face, the ore being exactly the same as that found in the Confidence. This is a good evidence that the ore body goes down to a depth of at least 1,000 feet, as the Minietta, which is similarly situated, had on the opposite or south side of the hill, has also similar ore.

LAKE.

GREAT EASTERN MINE.—Lake County Bee, April 27: A short visit to the Great Eastern mine last week enables us to report all alive. Movements being inaugurated by Superintendent Craven are looking toward the erection of a furnace of more adequate capacity than the one now in use. We found a very superior quality of ore on the dumps, and the miners report the recent discovery of a large body of metal of uncommon richness. This mine is most conveniently located on the Calistoga and Middletown road; the main shaft not

being over 200 feet from that thoroughfare. The Great Western mine will put up several fine ore furnaces the coming season. The construction of these, should they prove as practicable as expected, will materially reduce the cost of the reduction of fine ores at this mine.

NEW MINES.—Vallejo Chronicle, April 29: Mr. George Montgomery, the discoverer of the new gold and silver bearing rock in Lake county, was in town Thursday, and from him we learn some particulars. The ledge is found about seven miles north of Middletown, in a region thickly covered with brush, and can be traced two miles and a half. It is from 10 to 15 feet wide, as shown in the places where it crosses ravines. Particles of gold can be distinctly seen in the rock by the naked eye, and it contains both gold and silver, and is said to somewhat resemble Crown Point rock. No regular assay has yet been made, but Mr. Montgomery went down to San Francisco to-day with specimens to have one made. Montgomery is, we believe, an old prospector, but this ledge he came upon quite accidentally, having been in the region only two days. Besides his claim, as many as 20 others have been taken up, and a great deal of excitement reigned in that section when he left. James Haley is one of the holders of claims. It is expected some San Francisco parties will be interested in a company to work the ledge, although no details have yet been arranged.

MARIPOSA.

MINING ITEMS.—Mariposa Gazette, April 29: We learn that Messrs. Tiffany & Hepburn, who have bonded the Blue Lead and Scanlan quartz mines, above Coulterville, in this county, are progressing rapidly with their work in erecting buildings and machinery upon them, with a view to thoroughly prospect, and ascertain their richness in the precious ore, which they are known to contain in greater or less quantities. On the Blue Lead they are sinking a new shaft, and preparing to construct hoisting works, the machinery for which is on its way up from San Francisco to that locality. On the Scanlan mine, they expect to run the tunnel by means of a Burleigh drill, with a compressed air power, by means of which the wealth of this mine can soon be ascertained.

EXTRAORDINARY.—Messrs. Lamb & Adams have struck a rich lead of gold bearing quartz rock, about one-fourth of a mile in an easterly direction from the Blue Lead and works of Messrs. Tiffany & Hepburn, which is supposed to be a continuation of the same vein. This vein is about 15 inches thick, and prospects from \$80 to \$100 per ton.

FERROUS MINE.—The Ferguson mine, situated on the main Mariposa river, which formerly yielded its thousands of dollars in gold, but by some mismanagement has been allowed to remain idle for some years past, has been purchased by Mr. Ferguson, one of the original proprietors, who is about to resume work on it.

MAXWELL'S CREEK GOLD MINING COMPANY.—These works, situated near Coulterville, are progressing finely. They have quite a number of men employed getting out ore, cutting wood, and repairing roads, and will soon commence crushing. There are two veins, which are known respectively as the "Potosi" and "Mary Harrison." Rich ore has recently been struck in the latter, which, together with that already taken from the Potosi mine, gives assurance of a golden harvest to the company.

NAPA.

CONSOLIDATION.—St. Helena Star, April 29: From Mr. Daniel Patten, Superintendent of the Phoenix, who went to the city Monday, we learn that the Phoenix, Washington and Red Hill mining companies, in the upper end of Pope valley, have consolidated under the name of the Pope Valley quicksilver mining company. The Board will organize next week, when the property of the old corporations will be conveyed to them for the new company. The Phoenix, it may be here remarked, has not yet sold its last run of quicksilver, but is keeping the amount—42,000 pounds—for a better price than at present prevails.

THE ERNA MINING COMPANY.—Napa Register, April 29: The new directors of the Erna mining company, which has recently been reorganized, have held a meeting since their recent examination of the property, and consulted as to what should be done with it. The future course of action has not been fully determined upon; but it was decided to sell the pumping apparatus at the Valley mine; and it is also contemplated to move the furnace from the Valley to the Silver Bow. The mine is the best mine of the three which were consolidated under the name of the Erna, and is supposed to be a good mine and susceptible of profitable development. Some \$40,000 or \$50,000 worth of ore were taken from it under the old management.

PLACER.

ECLIPSE MINE.—Placer Argus, April 29: We learn that the development of the Eclipse mine, near Ophir, is in full progress, and that there is every prospect of its turning out one of the best paying mines in the Ophir district. The air shaft, to connect with the main shaft at the 100-ft level, is down 75 feet and will soon connect. The ledge at the depth of 100 feet is four feet wide and is yielding ore plentifully, and about \$10 per ton. The ledge is richly mined and abundant there is no trouble in making it pay. The mine is under the superintendence of C. A. Cooper, Esq., and is regarded as one of the most promising in the county.

MINING ITEMS.—Dutch Flat Forum, April 29: The break in the ditch of the South Yuba canal company, mentioned in our last issue, was repaired last week and water passed again. The water was carried away from the break, carrying away portions of a high trestle work, and breaking the ditch of the Miners' ditch company, which at this point is situated below it on the same hillside. The break in the latter ditch was repaired and water running within 24 hours. The former, however, was a more serious affair and has not been repaired at the time of writing. Great damage has not been reached, but these leaks are much to be regretted, as now is the harvest time of the hydraulic miner. The Polar Star claim, the object of much interest at present, has not, we are informed, been able to wash but 22 hours during the past week, owing to the break in the ditch of the South Yuba canal company, mentioned above. The Summerett and Miami claims are both idle from the same cause. The Central claim closed up on the 19th, and the Pacific on the 20th inst. The returns from each being the largest for the season, considering the number of days washing. Both having been refitted, resumed washing yesterday. The Gold Run claim cleaned up on Saturday, yielding quite a satisfactory product. The Cedar and Indian Hill claims are washing. The claims are working rapidly down toward the bedrock, where the rich deposit lies. The Yankee continues washing, using water about 18 hours a day to good advantage. This has been a hard nut to crack thus far this season owing to the great overlying rock and clay slide which has been constantly moving down over the face of the gravel. But as the water is being used to preserve the face and energy, this has been so far removed that the claim is in a very promising condition, and may be expected to make a big showing the balance of the season. The Badger claim has been using water about five hours per day, washing down a cut. The bed-rock having been reached, powder drifts are now being run to more rapidly open the pit. This claim promises well this season. Everything is in full blast in the mines of Little York and Liberty Hill.

PLUMAS.

LA PORTE AND VICINITY.—Plumas National, April 27: Mr. S. S. Russell, of La Porte, arrived in town on Wednesday last, and gave us a call. He says the past winter in that section has "knocked the spots" off from everything ever before known to the oldest inhabitants, and although spring has arrived, the signs of winter are still plenty. The snow is six or seven feet deep in the streets of La Porte, but is fast settling down. It is hard and solid, and a man can travel on the crust at

most as well as on the ground. The water has started, and almost all the hydraulic claims are in full blast. Provisions are getting scarce, and there is not a sack of flour for sale in any of the stores of La Porte, Gibsonville or Howland Flat. Potatoes are being brought from below, and sold at six cents. The miners are calculating on the water lasting till August, and have high hopes of a successful season. Mr. J. M. Daughters is in charge of Conly & Gowell's claims, and Mr. Gowell is expected up at any time. The Citybank company are at work cleaning out the old tunnel to furnish better air.

SISKIYOU.

SOUTH FORK OF SALMON.—Yreka Union, April 15: We learn that the mining prospects of the South fork of Salmon river are looking up finely, and work is being resumed up and down this stream with renewed vigor. Several new diggings have been struck, which pay largely and give evidence that there is plenty of new ground in that locality that will pay rich if worked. Graham & Gosh have lately taken up a claim about two miles below Fairbald, and take out about three bunches of the ore. One bunch, which they took out of a head of water they took out \$130. The claim on what is known as the second bench. There is no doubt of a good pay stream running along this second bench. Lewis Friday & Co., on Methodist creek, are doing very well. This company have now got a ditch of water running on to their claim and will take out the dust in large quantities. Egbert, on Methodist creek, has got a hydraulic claim, and has just washed away the dirt. He has prospected and found the pay channel underneath and expects to shortly reach it with hydraulic. Boston & Co. have got a good claim on Graham gulch. They have got plenty of water now and can take out \$100 a week to the hand. Brookins & Lewis have struck a good spot on Indian bar, and are taking out extremely good prospects. The water is doing well, and everything in the present indicates a lively mining season on the South Fork this year. There is plenty of good ground in that locality yet, and all it wants is a little energy and perseverance in prospecting to find it.

WORK COMMENCED.—Work was resumed on the Norfolk quartz ledge at Coulterville on Monday last. This great difficulty this company has met with in the past has been the water, the ledge lying so flat that the greatest difficulty was experienced in keeping it clear of water so that the men could work. The company have now started to run a tunnel on the south side of the mountain, and it is expected that this will entirely drain the mine. Work will now be pushed vigorously forward. At the place where the new tunnel has been started the ledge is a foot and a half wide, the rock is streaked black and white, and prospects first-rate. The last rock taken from the ledge—about 100 tons—paid when crushed about \$23 per ton. The Lodi, on the opposite side of Rocky gulch from the Norfolk, is lying idle at present, but work will no doubt be resumed in an early day. The last work done on this ledge developed some very rich rock.

STRUCK A GOOD LENS.—We learn that the proprietors of the old Mooklunburg quartz ledge, Messrs. McCann, Isenbeck and Walters, have struck a three-foot ledge of excellent quartz in their mine, and will soon have enough out to start up the mill belonging to the company. This ledge and mill is on the middle fork of the Redding, and when worked will make much. The former proprietors ran a tunnel and sunk a shaft on what they thought was the ledge, but what they took to be the actual walls of the ledge was merely a false wall and one of the walls of the ledge proper. The new proprietors' breaking through what the former proprietors supposed to be the hanging wall of the ledge have found a ledge of excellent quartz three feet thick and they have every prospect of having an extremely good thing.

THE EVENING STAR.—We learn that the prospects of the above mine, in the Salmon section, are as promising as ever, and every four weeks the company's mill furnishes its full quota of billion to its proprietors. This mine is considered by men who know what they are talking about, as being one of the most valuable mines in the State. They have a big ledge of excellent rock which pays with the utmost regularity.

TULARE.

SALE OF MINING STOCK.—Visalia Delta, April 27: Most of the stock issued by the New England tunnel and smelting company to holders in Tulare county under date of April 13th in payment of delinquent assessment, a very considerable portion of this stock was issued in payment for labor on the company's mill. The nominal valuation of the stock when issued was \$3 per share, or a share for a day's labor, though the face of the stock is \$100 per share. Much of the best mining property of Mineral King mining district was purchased with it at a valuation of \$3 per share, and upon the stipulation that the stock was non-assessable. The supreme court has decided that all stock is assessable, and now an assessment of 10 cents on the share causes it to be sold. It would seem that when the company was organized, the law was not complied with in the matter of paying in the 10 per cent, and that no percentage whatever was paid for it. We hear, however, upon the latest news, that the stock is now assessable. The company is now taking in new stock, and the holders of the old stock, which is to come off May 2d, such men as Senator Stewart, Thompson, Richardson, Rosecrans, Morgan, Smith, Munshue and others figure largely. Several of these men are members of the San Francisco stock board. The recent assessment leaves the company with several thousands of dollars on hand, and it is hoped that a new set of officials will go on with the development of the company's mines.

TUOLUMNE.

TRUMBULL.—Near this locality is the Trumbull vein and mine, which was located by David Trumbull, many years ago, and has been tenaciously held on to by him during that time. Mr. Trumbull is an experienced miner, and is sanguine as to the richness of his mine, and expects to live to see it fairly developed and listed with other first-class mines of the county and State. Mr. Trumbull is the inventor of an improved arastra, which requires but a small capital to utilize, and would no doubt prove a success, and add materially to the facilities for grinding and amalgamating quartz rock, and save a greater percentage of rock than any other mode or process at this time in general use by which gold has been extracted from quartz rock since its discovery in California.

MARTIN & WALLING.—This is one of the oldest mines that has been worked in the county, and in years gone by was famous for its productiveness. It is now incorporated under the name of Martin & Walling mill and mining company. Since its incorporation they have added hoisting works, and have re-umbered the old shaft, which was about 140 feet deep to the tunnel formerly run by the original locators. Work on the mine was again resumed in March last, by continuing the main shaft down 110 feet, which makes the shaft 250 feet in depth. By running a level 35 feet from the bottom of the shaft, the old shaft was reached, which is about three feet thick, and will pay from \$60 to \$70 per ton. As soon as the level is completed the company will extract ore as fast as possible; at the same time a 10-stamp mill will be attached to the hoisting works, which are run by steam power.

Nevada.

WASHOE DISTRICT.

JUSTICE.—Gold Hill News, April 27: The drift south at the 800-ft level will come to a connection with the drift north from the bottom of the winze from the 600-ft level in about a week. The ore here and at the 400 and 600-ft levels are of the best quality and keeping the mill steadily running. Another mill will

be put in operation on the ore from these levels next month.

HALE & NORCROSS.—An immense excavation has been made and is being filled with stone for a foundation on which to place the heavy pumping machinery now arriving. The shaft has been placed in the best possible condition, and is now as straight and smooth from top to bottom as it is possible for such a piece of work to be. When this machinery is once in good running order the Hale & Norcross will be in a much better condition for good deep sinking than ever before.

IMPERIAL.—The face of the north drift on the 2000-ft level is still in rich ore. The drift is being steadily advanced toward the Alpha lode. A station has been opened in the south drift on the 1900-ft level, and a winze started to connect with a drift now being run in Confidence ground on the 1740-ft level of the Yellow Jacket.

BEST & BELCHER.—The connecting drift with the Gould & Curry on the 1700-ft level is being put in excellent repair.

CON. VIRGINIA.—Daily yield, 550 tons of ore. This is crushed at the mills as fast as extracted. The yield of bullion for April will reach somewhere between \$3,300,000 and \$2,600,000. The ore breasts were never looking better or the mine more prosperous than now. Had the company the necessary mills the yield could be easily doubled in a single month. Sinking the C. & O. shaft is making excellent progress, considering the great size of the excavation necessary and the large amount of water to drain as the work progresses. The average rate of sinking is nearly three feet per day. The pump is hoisting about 40 inches of water, but the bottom is now confined to within eight or ten feet of the top of the shaft, showing conclusively that the largest part of the body has already been drained.

CALIFORNIA.—On the 1400-ft level the north drift has been thoroughly retempered and is again being pressed steadily ahead to connect with the Ophir. This drift has yet about 100 feet to run to complete the connection. On the 1500-ft level the north drift is also being driven forward to make an air connection at that point with the Ophir. Sinking the winze below cross-cut No. 6, on the 1550-ft level, is making good headway.

OPHIR.—Daily yield, 150 tons of ore. This ore is being crushed at the mills and is yielding a very handsome profit. The requisite number of mills have been obtained and the mine is now in a position to produce regular monthly dividends in a very short time. The ore breasts on the 1600-ft level are looking splendid and promise a goodly yield for many months to come. The fourth compartment of the shaft is completed down to the 1465-ft level, and the lucille hoisting machinery is now in the best possible condition for driving the developments on the lower levels. This is a matter of great encouragement, as it was a positive necessity that this work should be accomplished before the development of the deep levels of the mine could be accomplished to any material advantage whatever. Now that it is done some good work may be looked for. Cleaning out and repairing the drifts on the 1700-ft level is making rapid progress. On the 1100-ft level the south drift is still in quartz and ore, and will soon have opened a considerable extent of ground, ready to open and cross-cut the ledge.

WARD.—The foundations for the steam boilers and other machinery are being pushed rapidly to completion. The south drift on the 1000-ft level of the Julia has been started up and is being pushed ahead to prospect the Ward ledge at that point. This is a very important move, as it will not only determine the value of the ledge, but the shaft can be sunk to that depth, will afford a means of ventilation.

YELLOW JACKET.—The north and south drifts from cross-cut No. 3 on the 1940-ft level are still being driven ahead on the ore formation—one penetrating northward and the other southward. Cross-cuts Nos. 1 and 2 on the 1940-ft level are being steadily pushed ahead to prospect the ore vein south of cross-cut No. 3. The prospect that the vein is about 100 feet from the faces of both these drifts is about as good as the mine. The east cross-cut in the Confidence ground on the 1740-ft level is in a mixture of quartz and porphyry.

SILVER HILL.—The north and south prospecting drifts on the 1500-ft level are steadily advancing with favorable indications each way. The prospecting drifts and cross-cuts on the 1250-ft level are without change of material interest. Sinking the winze below the 700-ft level of the shaft is in connection with the south drift on the 1250-ft level, is also making good progress.

NORTH CON. VIRGINIA.—Sinking the main shaft is going steadily forward, the bottom still in porphyry, mixed with white quartz of a very hopeful character. This quartz carries a large amount of pyrites of iron.

SENIOR.—The use of the new hoisting cable was commenced to-day. This gives much better facilities for hoisting. The shaft is nearly drained and sinking will be resumed in a day or two.

BULLION.—The black dyke and porphyry in the face of the northeast drift on the 2000-ft level is getting much softer and begins to show evident signs of soon giving place to ledge material. The north drift on the 1400-ft level is again being steadily advanced, the face in very favorable ground.

MEXICAN.—The north drift on the 1465-ft level is steadily advancing along the east clay wall of the ledge, still finding in its course streaks and spots of very favorable looking quartz and ore. Preparations are now being made to commence cross-cutting the ore vein at different points along this drift in a very short time. When this is done there is little doubt that some valuable developments will be made.

KNOCKBROCK.—Sinking the main shaft is making excellent progress, the bottom being in ground of a little softer character. Numerous and very promising streaks of quartz are being encountered in the bottom of the shaft, which seem to show larger and much more solid bodies in close proximity, which may be cut into almost any day. There is a slight increase of water.

UNION CON.—The quartz in the face of the north drift on the 1350-ft level is still showing favorably for a broader and better development of the ledge and ore formation going northward.

UTAH.—Sinking the main shaft is making the usual steady progress, the bottom still in ground of a character that not only admits of a fair rate of speed, but which is having the shaft run on one of the smoothest and best working shafts on the line of the Comstock. The flow of water is still strong.

AMAZON CON.—The main south drift on the 300-ft level has penetrated the ore vein a distance of 40 feet from the station, at which point the ledge is evidently widening, with very flattering indications of the development of ore in large bodies.

BELCHER.—Daily yield, 450 tons of ore, keeping the mill steadily running. The ore breasts are looking well and continue to afford an abundance of good milling ore. The erection of the new and powerful pumping machinery is going rapidly forward.

PROSPECT.—Ten feet has been added to the depth of the shaft since last regular report. The bottom is in favorable working ground. No increase of water.

LEVATHAN.—The shaft having passed through the ore vein, mentioned heretofore, a station is being opened at the 600-ft level for a drift into the ore body.

KOSUTH.—The opening up the 600-ft level is steadily progressing in the most favorable manner possible.

GLOBE CONSOLIDATED.—The machinery and works are now in the best possible condition for a steady prosecution of the development of the ledge.

LADY BRYAN.—The work of preparing for the erection of the new and powerful pumping machinery is going steadily forward. The excavations have been commenced.

SUPERIOR.—Shaft down 90 feet, with the bottom in very encouraging looking vein material. The water increases, slightly interfering with the progress of the work.

BALTIMORE AND AMERICAN FLAT.—The 1250-ft station is opened and a drift has been started to prospect the ledge at that point. The face of the south drift on the 1050-ft level is still in quartz of a favorable character.

NORTH CARBON.—The new machinery for the hoisting

works is being placed in working position as fast as possible, and will be ready to start up in a few days.

FLORIDA.—The new machinery works as well as could be desired, and the drift at the 300-ft level is getting into good working shape.

OVERMAN.—Sinking the main shaft is making fair progress. The flow of water is still great but is steadily drained by the pumps.

SAVAGE.—The foundations for the new pumping machinery are rapidly approaching completion, and the machinery is fast being erected.

CHOLLAR-POKOR.—Sinking the combination shaft is making excellent progress.

SILVER CITY.—The management of this mine having changed hands, different arrangements are being made for working it, of which we shall be able to speak more definitely hereafter.

TWIN PEAKS.—The fine ore vein found in the shaft improves as greater depth is attained, showing wider and giving better assays.

LADY WASHINGTON.—The material at the bottom of the shaft shows considerable improvement. The whole bottom is in vein matter of the most encouraging character. It gives low assays in gold and silver, and is evidently leading to something good. Water shows a slight increase, but the pump handles it with the most perfect ease.

JULIA.—The main southwest drift, on the 1600-ft level, is steadily advancing at the rate of four feet per day, the rock being much softer than for some time past. The south drift from this main drift is steadily advancing, the face in quartz and low grade ore of a very favorable description.

GLASGOW.—The north drift, on the 300-ft level, is now in a distance of 46 feet. The entire width of the vein cannot be determined until everything is in readiness to cross-cut. During the week this drift encountered a streak of white quartz and ore rich with sulphurets of silver. This streak is gradually widening.

COSMOPOLITAN.—The main tunnel or adit is being pushed ahead, following the ore vein northward. The face is in streaks of good ore and porphyry. It will be followed to the north line of the claim. The upraise above the tunnel is getting along pretty well toward the surface, being up nearly half-way. It is in very good ore, some streaks which give good assays.

DARTMOUTH.—Driving the south drift on the 300-ft level to connect with the Kosuth for ventilation purposes is making excellent progress.

MORNING STAR.—The water has been drained from the main incline, and the sinking is again making good progress.

SILVER HILL.—Sinking the shaft is making steady progress, the bottom in good black ground.

RED AND WHITE ORES.—Shaft being sunk at a very good rate of progress, with the bottom in quartz, clay and porphyry of the most encouraging description.

CALEDONIA.—The flow of water causes some trouble but does not check or impede the progress.

NEVADA.—Better streaks of ore are coming in at the face of the north drift, showing increasing indications of nearing the main ore chimney.

ORONAGO GOLD HILL.—The retempering of the shaft will soon be completed.

MINT.—Sinking the main shaft is going ahead with renewed vigor, the bottom in soft working ground.

TRONAN.—The buildings are finished and the new steam machinery is nearly ready to start up.

PHIL. SHEPARD.—Everything is in readiness to again resume the thorough development of the mine.

(Continued on Page 300.)

CONSOLIDATED VIRGINIA MILL.—Almost the entire machinery for the rebuilding of the fine 60-stamp mill, destroyed by the fire last October, is on the ground; and as soon as the heavy timbers necessary can be obtained from the mountains its erection will be pressed to completion with all possible vigor. A new and wise plan has been adopted in regard to its restoration. A large amalgamating mill, similar to that of the California, will be erected on the site of the old mill, but the battery mill, which it is intended to make an 80-stamp mill, will be erected just below the C. & C. shaft, so as to receive its supply of ore direct from the shaft without any cost of transportation whatever. When the battery and pan mill are each finished, by a simple change of sluices from the California battery mill to the new Consolidated amalgamating mill, it will be supplied with the crushed ore from the upper batteries and the California pan mill with ore from the lower batteries, the whole forming one of the best and most economical arrangements possible. At both the C. & C. shaft and the California mill, large excavations are being made to put in condensing cylinders of great power, which will add greatly to the utility and strength of the works. The foundations are also being laid at the C. & C. shaft for six compressors of the largest and best patterns.

THE BONANZA.—Here is what the Gold Hill News says of the California mine in its latest "Mining Summary": Daily yield, 250 tons of ore, keeping the mill steadily running. The crushing of this ore is now adding from \$50,000 to \$60,000 worth of bullion per day to the product of the Comstock. The total product of bullion for April, with this one mill alone, will be over \$1,600,000, if it does not reach \$1,700,000. As for the richness of the ore these figures speak for themselves and need no explanation from us. The mine is just beginning to be opened, and, to confine ourselves to the simple truth, the only drawback yet experienced in its workings is to find ore of a sufficiently poor character to mix with the richer ore to keep the grade of the ore down to a sufficiently poor standard to amalgamate well. If there are any who have the temerity to doubt the truth of this assertion, we hold ourselves ready to substantiate every word of what we say. It will be seen that the California can easily make a dividend in May if the managers so desire. Whether they will or not is yet a matter of speculation, as those matters are decided by the board of trustees in San Francisco, and they have at least 10 days yet in which to deliberate as to what course they will pursue.

GOODMAN & Co. have purchased three acres of land at Mark West, lying adjacent to the railroad, and intend starting a large manufactory of wagons, carriages and agricultural implements.

WORK is progressing fairly on the narrow gauge between Nevada City and Grass Valley. The work will be completed on the 15th of May.

Mining Improvements in Oregon.

The unusually favorable mining season with which we have been blessed, says the Oregon *Sentinel*, has stimulated private enterprise to an extent that promises future good results, and will terminate, undoubtedly, in at least a partial restoration of the camp. So many years of drouth in succession served to deplete effort in prospecting, as well as to deter capital from undertaking new enterprises which would otherwise have been brought to completion long ago. But as we have said, new life has been infused into the camp, partially by the favorable season, and partially by example afforded in the introduction of improved methods of working placer ground.

A large extent of rich ground has for many years been known to exist in various localities near this place, but until lately has been considered unavailable by reason of the supposed great difficulty in procuring water and the impossibility of obtaining sufficient "dump," farmers, of course, being unwilling to have their ranches destroyed or damaged by the vast bodies of "tailings" which would have been deposited upon them by the old method of hydraulic. But these obstacles have to a great extent disappeared as improved methods have been introduced. A few days ago, J. S. Howard, surveyor, and a party of assistants made a preliminary survey of a ditch line between the headwaters of Applegate and the rich but supposed unavailable camp of Sterling, a few miles southward from this place. They not only found the line entirely feasible, but also discovered that sufficient water for a good sized canal could be procured from Applegate and brought to Sterling with a fall of 250 to 450 feet on the highest ground in that camp. From one fork of Applegate (known as Little Applegate) there can at this time be procured 2,500 inches of water, and by extending the ditch a short distance further that much or more water could be procured at all seasons of the year, which by reserving in the dry season could be made to answer for working the whole camp the entire year. The question of "dump" has never interfered there, as there is a fall into main Applegate of at least 150 feet, with a volume of water in that stream sufficient at all times to keep the dump clear. The proposed ditch is, between the mines and where water is first reached, twenty-two and three-quarter miles. This procures 2,500 inches at this time, and by a short extension, to another fork, takes in as much or more than double that amount.

We are informed that this preliminary survey was made at the instance of parties fully able to construct the work, and now that its feasibility is demonstrated there remains nothing to be done but to arrange preliminaries for a commencement of the work. Besides this, the construction of the proposed ditch will render available for grazing land, on the tops of bald mountains which has hitherto been useless by reason of a scarcity of water.

On Monday morning last the same gentleman and a corps of assistants began the work of final survey on a ditch proposed by John Orth, which will take water from Griffin creek and be of eight or nine miles in length. The size of the ditch has not yet been determined upon, but will be constructed so as to carry all the water that can be taken from the stream as well as the smaller brooks in the line of its transit. This will afford water for the working of probably a greater extent of ground than the Applegate ditch, much of which is known to be very rich. It will be intended to work that famous tract known as "Johnny Orth's pasture," which of itself embraces area sufficient to last many years, and which has been prospected to a depth of 80 to 100 feet, with good pay the entire depth and the bedrock yet untouched. This tract lies in the line of the "old channel" which runs through these mountains from east to west, and from which doubtless came all, or nearly all, the gold found in the various rich creeks and gulches about here, all of which rise in or cut through this channel from Galice and Briggs' creeks in Josephine county to the Klamath river in California. It has been worked in the low places, while the high mountains over which it passes, and even many lesser elevations, have been untouched from want of water. These ditches will furnish water to work ground thousands of feet higher than has heretofore been touched. On the high mountain west of town, more than a thousand feet above running water, Jos. Blatt has been mining for many years by drawing water from a well and rocking, making fair wages all the time, we are informed, while as high as 75 cents have been obtained to a flour sack of dirt taken from shafts sunk in Orth's pasture. Old prospectors say they know of many small tracts of ground on the line of Orth & Co.'s ditch that will pay from \$8 to \$16, and even more, to the man per day by the ordinary method of ground sluicing. All these will be worked as soon as water can be brought upon them.

When once these two enterprises alone are brought to completion, there will be as good a mining camp here as has ever been, and they will endure much longer than the creek and gulch mining, which once made this camp a famous and rich "bonanza" for the pioneers of '52.

An inch depth of rain on an acre yields 6,272, 640 cubic inches of water, which, at 277.24 cubic inches to the gallon, makes 22,622.5 gallons, or 226,225 pounds.

SEVERAL Cornish miners left Austin last week for New Mexico.

Mining at Happy Camp.

From a two column and a half communication of "Teutonic" in the Crescent City *Courier*, we glean the following mining items from Happy Camp and vicinity:

Mining, of course, is prospected at this season of the year with a vigor that knows of no pause or delay, and as usual, some are doing well, some bad, and some indifferent. The H. O. H. M. company, who for a long time were the held in the matter of taking out the "caro-seed," is about to relinquish that figurative appendage to the Chinese creek claim, owned by Mr. B. Reeves, which has produced, I am informed, thus far, \$5,000, at a daily expense of running the claim of about \$30. The H. C. H. M. company, however, has done well, too, although the last two "clean-ups" left but a small surplus after deducting the running expenses of the claim. Out of the first nine days' run they realized over \$2,000, and the next "clean-up" amounted to nearly \$2,000. At Bonker hill, after a spell of inaction, mining operations are prosecuted with a fair chance of success, and on Muk-a-Muk flat, which is owned and worked by the same company, things look hopeful, if not bright. L. B. Grider, who operates upon the bank of Grider's creek, among a mass of holders, is still inflexible in his belief, despite his so-so success thus far, that he will strike it rich, and has promised your correspondent to let him have a look at the first half bushel measure he succeeds in filling with the "dithy lucre." Jerry Lane, on Wingate hill, thus far has done poorly, barely making expenses. Many things, impossible in their nature to foresee or forestall, brought it about, prominent among which were the unusually early approach of the rainy season, and the continual breaking of his new ditch. The owners of Buzzard hill and Patrick bar talk about continuing their forces, for the purpose of conveying the waters of Moor's creek to Patrick's bar, where Tama says rich diggings exist. S. S. Richardson is busy in bringing his energies to bear upon his recent ditch, which ever and anon threatens to leave him, and take a trip down the Klamath. Up on Indian creek the miners are pretty effectually snowed in, which precludes mining operations, and the same is the case with those on Elk creek.

PRACTICAL EDUCATION IN PARIS.—A correspondent of the *Moniteur Industriel* communicates to that journal a description of a school of practical instruction, situated in one of the suburbs of Paris. The writer outlines a system of education in which the future occupations of the pupils are kept steadily in view, and where every step of progress in study marks an advance in real knowledge. A few instances will best show the method of instruction. Suppose a lesson in botany is to be given, and that the special subject is some textile plant. The pupil sees, in the botanic garden attached to the school, a few stalks of hemp growing. The botanic character of the plant is explained to him; he is told how it grows, and what are the conditions favorable to its growth; then he is shown how it is treated in order to obtain the fiber, how the latter is spun, woven, etc. In giving instruction on minerals, a like course is followed. For instance, the subject is iron ore: various kinds of ore are exhibited, the processes are explained, by means of models and designs, of the reduction of iron and its manufacture. So in mechanics: models of machinery are shown and explained; better still, the pupil is taken to the workshops, where he sees various kinds of machines in operation. His understanding of things is tested by questions and by being required to draw the objects he has been looking at, and to explain their working. Topography and geography are taught in the same common sense way, the pupil being led to map out an ever widening area.

THE LARGEST PHOTOGRAPHS IN THE WORLD.—Mr. B. O. Holtermann, the well known gold miner, and one of the richest men in the colony, claims to have produced the largest photographic views in the world. He has two views of Sydney and harbor, each five feet by three feet two inches, and two of four feet six inches by three feet two inches. These photographs, Mr. Holtermann claims, are the largest ever produced from single negatives. They give a complete view of the city and harbor of Sydney from Garden island to Long Nose. No. 1 negative, which is five feet by three feet two inches, takes in the space from Garden island to Dawes' point; the second, of the same size, embraces from Dawes' point to Miller's point; the two others, each four feet six inches, showing from Miller's point to Long Nose. Apart from the size of the pictures, they are splendid specimens of the photographer's art, the outlines being sharp and clear and the various objects shown coming out prominently before the eye. The difficulty of producing pictures of such size can be best understood and appreciated by photographers.—*Sydney Evening News*.

J. F. THOMPSON, of Virginia, recently returned from a trip to Europe, where he visited many mines, becoming acquainted with valuable improvements in European mining systems which has proposed to utilize on the Comstock. These improvements consist principally in ventilating and pumping machinery.

The Seattle & Walla Walla railroad company have contracted with J. M. Colman, of Seattle, to complete the first section of 15 miles of their road, and the work will be commenced immediately.

USEFUL INFORMATION.

Chromium Glue and its Applications.

This consists of a tolerably concentrated solution of gelatine, to which has been added for every five parts of gelatine one part of chromate of lime in solution. This mixture has the property, on exposure to light, of becoming insoluble in water, a result due to the partial reduction of the chromic acid to a lower degree of oxidation; this property has already been utilized to a considerable extent in several of the recent processes for photo-lithography and photo-engraving.

Schwarz proposes this combination as a cement for glass vessels which have been broken. The surfaces of the vessel to be cemented are coated as uniformly as possible with the freshly prepared glue, and are then pressed firmly together and held in this position by means of thread. The vessel is then exposed to the light for several hours, at the expiration of which time the operation is complete.

Boiling water does not cause the article thus repaired to separate, having no effect upon the new combination, and the joint is hardly perceptible. Valuable vases or other articles, instead of being disfigured by the ordinary mastic cement, should be mended by this process. It has been suggested that microscopic slides may be finished with this material, with advantage over the ordinary asphaltum varnish.

Chromium glue may be also utilized in the manufacture of water-proof cloth and paper impervious to moisture. The fabric, to be treated, should be stretched upon a frame and immersed two or three times in the preparation, and exposed to the sun. Damp proof paper may be prepared by simply brushing over the surface with a thin solution prepared as above.

A singular application of this combination of glue and chromium was made during the Franco-German war in 1870. At that time the well known pea sausage, one of the most important articles of food used in the German army, was prepared daily in many thousands of skins. The preparation of the interior portion caused little difficulty, but so many skins were not easily supplied. As the supply fell short a substitute was sought in parchment paper—prepared by dipping, for a short time, blotting paper in sulphuric acid, then washing and drying it. This paper was used for the fabrication of sausage skins by doubling the sheet into the form of a cylinder and pasting the edges. But no glue or gum can resist the effect of boiling water in which the sausage had to be cooked, and so the artistic sausage skin fell asunder. Dr. Jacobsen suggested the use of chromium glue as a cement; the gelatine intended for the sausage skins was mixed with a minute portion of bichromate of potassium, and the part cemented exposed for a short time to the sun. The experiment succeeded perfectly, for the artificial skins endured boiling water exceedingly well. The number of sausage skins prepared in this way by the chemical operation of light amounted to many hundred thousands.—*The Laboratory.*

Coloring Brass.

In the following will be found valuable details relative to the coloring of brass. An orange tint, inclining to gold, is produced by first polishing the brass and then plunging it for a few seconds in a warm neutral solution of crystallized acetate of copper. Dipping into a bath of copper, the resulting tint is a grayish green, while a beautiful violet is obtained by immersing the metal for an instant in a solution of antimony and rubbing it with a stick covered with cotton. During this operation the brass should be heated to a degree just tolerable to the touch. A more appearance, vastly superior to that usually seen, is produced by boiling the object in a solution of sulphate of copper. There are two methods of procuring a black lacquer on the surface of brass. The first, which is usually employed by instrument makers, consists in polishing the object with tripoli and washing it with a mixture composed of nitrate of tin one part, chloride of gold two parts. Allow this wash to remain for 15 minutes, then wipe it off with a linen cloth. An excess of acid increases the intensity of the tint. In the second method, copper turnings are dissolved in nitric acid until the latter is saturated; the objects are immersed in the solution, cleaned, and subsequently heated moderately over a charcoal fire. This process must be repeated in order to produce a black color, as the first trial only gives a dark green. Finally, polish with olive oil. Much pains are taken to give objects "an English look." For this purpose, they are first heated to redness and then dipped in a weak solution of sulphuric acid. Afterward they are immersed in dilute nitric acid, thoroughly washed in water, and dried in sawdust. To effect a uniformity in the color, they are plunged in a bath consisting of two parts nitric acid and one part rain water, where they are suffered to remain for several minutes. Should the color not be free from spots and patches, the operations must be repeated until the desired effect is produced.

METHOD FOR DETERMINING THE VALUE OF COALS.—Mr. L. Thompson, M.R.C.S., publishes the following as a convenient method for getting the economic value of coals: The apparatus required is a small cast iron crucible about the size of a common tea-cup, and furnished with a lid. This crucible should be as light and thin as possible. The one the author

now uses weighs six ounces, holds four ounces of water, and cost one shilling. Having obtained a fair sample of the coal—which is rarely practicable except one cwt. has been crushed under edgestones—redness an ounce of this to an impalpable powder, and carefully mix ten grains of this with one-quarter ounce troy of common salt, previously dried, and then add and thoroughly mix with this one ounce troy of chromate of potash; place the mixture in the crucible, put on the lid, counterpoise the whole with great care in the scales; then, allowing the counterpoise to remain, place the crucible in a common fire where it may become dull red-hot, and allow it to continue so for a quarter of an hour; after which take the crucible from the fire, and when cold, place it again in the scales, and notice how many grains it has lost; then deducting from this the weight of the coal (10 grains), the remainder represents the quantity of oxygen carried off by the really useful combustible constituents of the coal. This he has found to vary in the coals supplied to the London market from 19 to 28.—*London Chemical News.*

HOW TO CLEAN A METAL CLOCK.—An English writer says: Dip a feather into common paraffine oil, such as is used for lamps, and touch up all the oily places of the clock, especially axles and holes; then let the clock stand a few hours, give more paraffine, and touch oftener if you think it is better for it. Afterward strew strong washing powder among the wheels, etc., and plunge the clock into a strong solution of the same in boiling water. Let it lie there in till the water gets cool enough to place your hands in, when with a toothbrush rubbed with soap wash out the dirt from the works. Afterward cleanse completely from all trace of soap and powder in plenty of warm water and the operation is complete.

PURIFYING WATER WITH ALUM.—Alum will only purify water from organic impurities, which it will precipitate in the same manner as it precipitates dissolved coloring matter in the manufacture of lakes from dye woods. One teaspoonful of pulverized alum in four gallons of water is sufficient. If the water contains such an amount of impurities that this quantity will not purify it it is unfit for drinking purposes. In the artificial manufacture of ice from Mississippi river water, at New Orleans, this method is employed to purify the water before freezing it.

TO SILVER CAST IRON.—To silver cast iron, 15 grains of nitrate of silver are dissolved in 250 grains of water, and 30 grains cyanide of potassium are added, when the solution is complete, the liquid is poured into 700 grains of water, wherein 15 grains of common salt have been previously dissolved. The cast iron intended to be silvered by this solution should, after having been well cleaned, be placed for a few minutes in a bath of nitric acid of 1.2 specific gravity just before being placed in the silvering fluid.

GOOD HEALTH.

Gelsemium Sempervirens in Neuralgia.

This article, which has had reputation in this country for neuralgia, has attracted little attention in Europe. It has been recently tried at the dispensary at Heidelberg by Dr. Jurasz, assistant physician, who has reported favorable results. Five minims of the tincture were given three times a day for three days to a man aged 30, who had been suffering for a week with neuralgia of the right supra-orbital nerve, which cured him. The same dose given for six days gave permanent relief to a woman who had had brachial neuralgia on the left side for more than a year and a half, and been treated with various other remedies without success.

Two other neuralgias of the fifth nerve were rapidly cured with five and ten minim doses; and a case of very severe sciatica on the right side in a man of 60, which had completely disabled him and confined him to bed, was quickly relieved by eight minim doses three times a day, and the patient was able in a fortnight to walk with a stick; the cure being completed by warm baths and the use of the constant current.

On the other hand, the gelsemium failed completely in two cases of muscular rheumatism, and in a case of long standing hemiplegia.

In no instance was any unpleasant effect observed, either on the circulatory or digestive organs; but the dose of 20 minims was never exceeded.—*Journal Medical Sciences.*

SWEET OIL FOR POISON.—A farmer writes to the *College Courier*: It is now over 20 years since I heard that sweet oil would cure the bite of a rattlesnake, not knowing that it would cure other kinds of poison. Practice and experience have taught me that it will cure poison of any kind, both on man and beast. The patient must take a spoonful of it internally, and bathe the wound for a cure. To cure a horse, it takes eight times as much as for a man. One of the most extreme cases of snake bite occurred 11 years ago. It had 30 days' standing, and the patient had been given up by his physicians. I gave him a spoonful of the oil, which effected a cure. It will cure blot in cattle caused by fresh clover. It will cure the stings of bees, spiders, or other insects; and persons who have been poisoned by a low running vine called ivy.

Dyspepsia from Eating Hot Bread.

Gen. Clingman tells some truths and offers suggestions about the causes and results of dyspepsia and indigestion, with special reference to hot, doughy bread, which will apply to all parts of the country. Read and heed: It has been said that the frying pan is an enemy of our people. There can be no doubt that it has slain thousands; but hot bread is the slayer of tens of thousands. While traveling in Europe for eight months, I saw nothing but cold bread, nor did I, while there, see anything that tended to induce me to believe that anybody in Europe had ever eaten a piece of hot bread. I invariably, however, found the bread good, and the people I saw appeared healthy and robust. Some, as the English and Germans, were especially so. With respect to the United States, the condition of things may be more strikingly and pointedly presented by reference to individual cases. Many ago years I stopped at a house of an acquaintance, and on seeing him I said "You are not looking as well as usual." "No," he replied, "I have the dyspepsia powerful bad." When dinner was ready there was an abundant supply of meats and well baked corn bread. There was also, however, something called biscuit, which was, in fact, rather warm dough, with much grease in it. I saw that my host ate this freely with his meats. I remarked that I did not wonder he had dyspepsia, for I could not live a month that way. I suggested that if he would eat well baked corn bread, or better still, light bread, he would not suffer as he was doing. He answered vehemently that he would rather die than eat cold bread. I replied: "This is a free country, and you have a right to die in this mode if you choose, and I have no doubt that you will soon die." Then I referred to cases in which I had known people to die from such practices. My cool mode of discussing the question evidently made an impression on his wife. Next summer, on meeting him, I said: "You are looking much better." "Yes," he replied, hurrying into a hearty laugh, "I followed your advice and took to eating light bread, and I am as well as I ever was in my life."

BREAKING DOWN.—Men often have their hands full, are overcrowded with business and drive hurriedly along at it, but they may not be overworked. We cannot always tell when we are overworked. A man does not always know himself, no more than he knows the strain on the mainspring of his watch that will break it. But there comes a time when it breaks—a click, a snap, and the watch stops. Men break down in this way. They go on, day after day, the pressure being harder each successive day, until the vital force gives out, and the machine stops. It is a great pity that the indications of this state of things cannot be seen beforehand, and if seen, regarded. It is one of the last things that men will admit to themselves, much less to others. They flatter themselves that it is only a little weariness of the flesh, which will pass off with a few hours' rest, when in fact, every nerve, power and resource is exhausted, and the system is driven to work by sheer force of the will. When the oil on the shaft or in the wheel wears on the revolving part, and soon will ruin it. The same is true of the human body.—*American Manufacturer.*

EFFECT OF THE SEASONS ON THE BODY.—The curious fact has recently been pointed out by Dr. B. W. Richardson that the changes of the seasons have a potent physical influence upon the body. Some years ago, in a convict establishment in England, a number of men were confined amid surroundings (of clothing, room, food, etc.) practically the same for each individual. The medical superintendent of the jail undertook investigations, extended over some nine years, and during which over 4,000 individuals were weighed. It was found that during the months of winter the body wastes, the loss of weight varying in increasing ratio; that during summer the body gains, the gain varying in an increasing ratio; and that the changes from gain to loss and from loss to gain are abrupt, and take place, the first at the beginning of September, and the second at the beginning of April. This is shown in the following figures, indicating the ratio of loss or gain: Loss: January 0.14, February 0.24, March 0.35. Gain: April 0.03, May 0.01, June 0.52, July 0.08, August 0.70. Loss: September 0.21, October 0.10, November (exception) a slight gain, December 0.03.

STENCILLING MATERIALS FOR PAINTERS' USE.—Stencilling is an art by which the painter can execute ornamental work very quickly. The articles required in making a stencil are a sheet of well sized writing paper, a lead pencil, and a sharp penknife. Fold the paper, allowing the edge of the fold to form the center of the pattern, then draw any desired design, leaving bare to hold the parts together. Place the paper upon a piece of glass and cut out the figure with a penknife. The tool used is a camel's hair brush with hair not over an inch long, bound with quill and wire on a round wooden handle. The small sizes are preferable. Color mixed with vinegar and sugar will be found best. The paint must be quite thick; and a small quantity only must be taken on the brush, and then well rubbed out on a dry plate before applying it to the work. Placing the stencil on the panel as desired, hold it down firmly, and rub over with the brush carefully until the cut portions of the figure are well coated. Then lift off the stencil and the work is completed.—*Scientific American.*

DOMESTIC ECONOMY.

Hints on Pastry Making.

The following hints on pastry making, by an old housekeeper, are worthy of study. The Americans are too much addicted to pastry, but since the taste is already formed, it remains only, in the preparation of such food, to make it as little injurious as possible by making it good.

The art of making paste requires a good memory, practice and dexterity; for it is principally from the method of mixing the various ingredients of which it is composed that paste acquires its good or bad qualities.

Before making paste wash the hands in hot water; touch the paste as little as possible, and roll it out little; the less the better. If paste be much wetted it will be tough.

A marble slab is better than a board to make paste on; both, together with the rolling pin, cutters and tins, should be kept very clean, as the least dust or hard paste left on either will spoil the whole.

The coolest part of the house and of the day should be chosen for the process during warm weather.

Flour for the finest paste should be dried and sifted, as should pounded white sugar.

Butter should be added to paste in very small pieces, unless otherwise directed.

If fresh butter be not used, break salt butter into pieces, wash it well in spring water to cleanse it from salt, squeeze it carefully, and dry it upon a soft cloth. Fresh butter should also be well worked to get out the butter-milk.

After the butter has been pressed and worked with a wooden knife on the pasteboard, press it very lightly with a clean soft cloth, to absorb the moisture. If good fresh butter is used, it will require very little, if any, working.

Lard is sometimes used instead of butter, but the saving is of very trifling importance when it is considered that, although lard will make paste light, it will neither be of an good color or flavor as when made with butter.

Dripping, especially from beef, when very sweet and clean, is often used for kitchen pies, and is, in this instance, a good substitute for butter, lard, etc.

In hot weather the butter should be broken into pieces and put into spring water, or into ice; but on no account put the paste into ice, else the butter in it will harden it, and in baking, melt, and separate from the paste.

The same thing happens in winter, when the butter has not been sufficiently worked, and the paste is rather soft; for, though the season be favorable to the making of paste, care must be taken to work the butter sufficiently.

In winter, paste should be made very firm, because the butter is then so; in summer, the paste should be made soft, as the butter is then the same.

It is important to work up paste lightly and gradually into a uniform body, no strength nor pressure being used.

It is necessary to lightly flour both sides of paste when you roll it, in order to prevent its turning gray in baking; but, if much flour be sprinkled on it, the paste will not be clear.

Attention to the rolling out is most important to make light puff-paste; if it be too light, it may be rolled out once or twice more than directed, as the folding mainly causes it to rise high and even.

Be sure, invariably, to roll puff-paste from you. Those who are not practised in making puff-paste should work the butter in by breaking it into small pieces, and covering the paste rolled out; dredge it lightly with flour, fold over the sides and ends, roll it out very thin, add the remainder of the butter, and fold and roll as before.

To insure lightness, paste should be set in the oven as soon after it is made as possible; on this account, the paste should not be begun to be made until the oven is half heated, which sometimes occupies an hour. If paste be left 20 minutes or more before it is baked, it will become dull and heavy.

Paste should be light, without being greasy; and baked of a fine color, without being burnt; therefore, to insure good baking requires attention.

Puff-paste requires a brisk oven; a moderate one will best make pies and tarts, pudding and biscuits. Regulation of heat, according to circumstances, is the main point in baking.

If the oven be too hot, the paste, besides being burned, will not rise well; and if it be too slack, the paste will be soddened; not rise and want color. Raised pies require the quickest oven.

When fruit pies are baked in iron ovens, the syrup is apt to boil out of them; to prevent this, set a few thin bricks on the bottom of the oven before it is heated; but this will not be requisite if the oven has a stone bottom.

Tart tins, cake molds and dishes should be well buttered before baking; articles to be baked on sheets should be placed on buttered paper.

APPLE PIE.—Take nice, tart apples—Spitz-enbergs are best, although Pippins, Greenings, Russets, etc., are excellent. Slice them; fill the under crust an inch thick; sprinkle sugar over them; add a spoonful or two of water; cover with a thin crust, and bake three-fourths of an hour in a moderate oven.

NOSE CHEAP PUDDING.—One quart of milk; four tablespoonfuls of flour; four eggs; six tablespoonfuls of sugar; nutmeg. Steam three-fourths of an hour.

A "FAMILY GATHERING."—We don't not our readers will be pleased to hear of a little "family gathering" of the proprietors and attachees of the Press and a few personal friends, which took place in this city on Saturday. An informal gathering was had at lunch time to bid God-speed to our senior editor, Mr. W. B. Ewer, on his journey to the Centennial. After a wholesome luncheon and friendly converse, a pleasant presentation took place, in which Mr. Ewer received a very handsome rosewood case, mounted with gold and quartz, with this inscription: "W. B. Ewer, A. M. 1876: From his Partners." The case was a model of handsome work from the store of Dewey & Jordan, 433 Montgomery street, San Francisco. It bears upon its head a sample of our richest produce and may express to our Eastern friends new evidence of our inexhaustible resources. As Mr. Ewer carries it on his journey it will assure him of the kind feeling of those he left behind him. And when he warlike amid the busy display to which he is going, let it support him with its own strength and with a consciousness that those from whom it came to him are waiting to welcome his return to his beloved Western home.

J. C. JAMES, the engineer who has done the surveying required in the Consolidated Virginia and California mines, says there is no foundation for the intimation that the Consolidated Virginia have been mining ore from the California ground. On the contrary, work in these mines is carried on as it would be if the companies had no interest in common.

Montana Mines.

There are a great many persons who have an impression that the mining interests of Montana amount to very little. They remember the halcyon days when the shallow placers of the Territory yielded fabulous amounts of gold, when fortunes were made in a few weeks, and the days of '49 in California were almost equalled. But these placers were mostly worked out some time since, and the miners have had harder work to get the gold and get less of it, too, than they used to. Still it is by no means the case that all the Montana surface diggings are worked out, and her quartz interests show greater activity than ever before. We had a conversation this week with a gentleman who has spent the last six months in Montana, and from him we have obtained some general facts of interest to the mining community.

In speaking of the placers, he says even in that line an improvement is manifest. There is an immense amount of ground which would pay but for two reasons: One is that it is so nearly level and the other is the difficulty of getting water. There is plenty of water everywhere, but the trouble is to get it high enough. The dam question, under these circumstances, is also a very difficult one to solve. Most of the early ditches were too short and constructed to feed limited areas of ground. But now they are building larger ditches to command higher ground, but such enterprises are expensive and require a large amount of capital, the same as in California, so ordinary working miners are unable to carry them out.

There are many places along the Missouri river where there are bars and bank washings, but they do not amount to much. However, if the stream could be turned, an immense amount of gold would in all probability be taken from the bars. Nothing but a very heavy operation could do anything in this direction. The big Alder gulch, which built up Virginia City, is claimed to have produced all the way from \$30,000,000 to \$70,000,000, and paid the whole length of 14 miles. They still work here every summer. Another famous canon, "Last Chance gulch," built up the city of Helena. In this gulch they are now building a long bedrock flume, which they are going to take all the way up. About a mile of it was built last summer. The gulch is very deep, and formerly pits were sunk and the dirt hoisted out. With the ditch they will be able to work much lower down and get on the bottom, where they could not work advantageously before. The ditch is being built by Mr. Chisholm, the owner of the water privileges. There are many other placer grounds all over the Territory, but those spoken of are the most prominent. In most instances it takes great trouble and heavy capital to get in the water, and get over the difficulty of lack of dump.

The quartz mining interests show steady improvement. There are gold mines there which have been worked a long time. The old Whit-latch Union mine was worked before Last Chance gulch was discovered. The number of copper mines worked is steadily increasing. Last winter was the first one in which some of these mines were worked continuously through the winter. All the ore from the copper mines is shipped down the river to St. Louis and Baltimore, none of it being worked in the Territory. From Helena to Benton—90 miles—it costs about \$10 per ton to haul it, and they ship it from Benton, the head of navigation, down the river for from \$7 to \$10 per ton. If the river is ever improved, Montana needs no great railroad, as the water highway would be the best. A bill has been passed by the Legislature, granting a right for a railroad from Helena to Benton. Below that the river runs through a flat country and spreads out over a wide surface in many places, where training walls or jetties are needed to deepen and confine the channel.

The gold were the first quartz mines worked. The surface quartz was worked out but they quit when they got to the pyrites. Then came the copper mining, which is now the rising interest. They are working these mines in four different localities, there being a number of different mines at each. To eliver more and more attention is being paid. In the early days of this class of mining the Washoe process was adopted, it having succeeded well with some of the Idaho mines as well as at its home. But the process was not successful, the ore were unfit for that method of treatment, or rather, the method was not the proper one. After working rather unsuccessfully for some years with raw ores, silver mining came to a standstill. There is now only one mill working by this process in the Territory—the Hope mill at Phillipsburg. Smelting was then tried, and at a considerable expense and loss. There is now only one furnace running periodically, which, when it can get the right ore, does very good work.

More attention is now being paid to roasting the ores, and two new mills for roasting and amalgamation were built since last summer. These are the "Farlin," at Butte, and the "Northwest," at Phillipsburg. There are also two mills operating by the Turner process—the "Centennial," at Butte, erected last winter, and the "Kemp" mill at Jefferson. The Turner process is pretty much the same

as the old patio; they use sulphate of iron instead of sulphate of copper.

The Northwest mill (which we described in detail in a recent issue) has three Bruckner cylinders and ten stamps. The Farlin mill has ten stamps and reverberatory furnaces. The Centennial and Kemp mills have each five stamps. All of these are silver mills, and our informant thinks they will make a success of the silver mining.

He thinks, moreover, that the country has been very poorly prospected. It has leached under the disadvantages of not having had a market for ore, and of having severe winters. Only first-class ore would stand shipment. It costs now to ship ore East, taking into consideration freight, interest, etc., about \$100 per ton, beside the very long time they have to wait for return. As to the lithology of the country, the main Rocky mountain range is granite flanked by limestone. The spurs which run out are covered with limestone, and the mines are found both in the granite and limestone.

Virginia City and Comstock Mines.

NUMBER ONE.

[By our Resident Correspondent.]

A protracted stay in Reno only strengthened the conviction that there is a bright prospect ahead for this active town. The rapid increase of the agricultural population, the advance in the price of land and the encouraging developments in the operations of the mining companies have given a good end-off to the spring business, and it might be supposed there was nothing else required to make the full measure of their wants. But they are by no means satisfied, and are earnestly disavowing the establishment of manufacturing enterprises, particularly that of a woolen mill, which, in view of the large quantity of wool that goes there in search of a market, and the water power furnished by the Truckee, would seem to be a suitable industry. Unfortunately, the location best adapted to this undertaking is practically beyond the reach of any useful purpose. This, the Nevada land and mining company's property, consists of a large tract of fine land in one of the best portions of the valley, a valuable water franchise and so ore mill not now operated. The water power here is ample for a large establishment and is ready for immediate use, while enough water remains to irrigate the whole tract and leave a surplus for sale. The mill building and some of the machinery remain in good condition, and could be readily converted into a factory of any kind. The other buildings are in a good state of preservation, some of which are commodious and well arranged dwellings. But all these advantages go for nothing while a complicated lawsuit hinders the sale and use of the property for any purpose. Any gentleman who desires the lasting gratitude of the dwellers in Reno can obtain it by untying this knot and placing the property with a clear title on the market.

As the passenger trains of the Virginia and Truckee railroad pass each way at night, there are but few persons who see anything of the country through which this wonderful road is built. A good opportunity is afforded for a day trip by laying over at Reno until 12 o'clock noon and taking the accommodation train, which makes the trip in about six hours. Although slow, it will not be found tedious, and a sight of this route will dissipate some of the false impressions which strangers are sure to get when they arrive at Virginia City just at daylight and see only barren mountains on every side. Then, too, the early morning is not the best time at which to arrive. When the Eastern tourist, or even the "Frisco man," wakes up and gets out of a warm car and, satchel in hand, tramps around these breezy hills in search of a lodging, and consumes a half day in finding one in which there is neither stove nor fireplace, his enthusiasm is endangered, and he is compelled to remind himself continually of the mines of wealth over which he is supposed to be trudging, in order to retain the necessary courage for those things which are in sight.

Since the fire the population has been too large for the number of houses, but they are rapidly being rebuilt, as are also the hotels, so that this state of things will not last long. A trip over the road by day shows that it passes for a large part of the way through fertile valleys. Fine grass and grain land is in sight all the way to Carson, and it is readily seen that an industrious population here could sustain a large number of workers in the metal-mined mountains around them. Hay, oats, potatoes and many other products give large returns, and are assuming more and more importance each year, making it evident that the purely mining towns will not in the future have to send so far for these necessities.

Many places of interest are pointed out along the way. At Hufaker's the Pacific flume company delivers its immense transportation of wood and lumber, which is all used here. Mr. Harst's (the superintendent of this company) invitation to take a ride down the flume was not accepted, for fear that the MINING AND SCI-

ENTIFIC PRESS might be temporarily left without a representative at Virginia City, and for the further reason that your correspondents are so little used to a speed of 18 miles in 15 minutes.

Several other flumes discharge their loads at various points, and soon a sulphurous smell denotes the proximity of Steamboat springs with its curious surroundings.

The sulphur works there are said to be among the most profitable enterprises in the State, and the proprietors do not seem in the least dismayed or discouraged by the opinion of some people that they are just over the lake of fire and brimstone.

Washoe City, the next place of any note, will be remembered by many for the bright anticipations it once had of large growth and permanent prosperity. Evidence of former industry are visible on all sides, now replaced by deserted stores and desolate dwellings. A fine view is afforded of Washoe lake in its whole extent, and a sight of this beautiful sheet of water in itself repays for the delay of the trip. Almost while taking the last look at the lake, the divide is passed which separates this from the Carson valley, and Carson City is in full view far below the bed of the road. This is one of the finest views on the route and Carson is probably the handsomest town in the State. The bird's-eye view from this elevation gives it much the appearance of a neat, well laid out New England town.

From Carson to Virginia we are principally engaged in winding and climbing up mountain ends winding and gliding down the other side, the road repeatedly doubling on itself until at last Gold Hill is in sight, apparently just across a ravine; but when the unsuspecting traveler thinks he is about to get there, he suddenly finds that his back is turned towards it and he is going in another direction. This, however, cannot last forever, and after a few more twists and turns he arrives first at Gold Hill and in a few minutes afterwards at Virginia City, thoroughly impressed with the difficulties encountered in building this railroad, and much pleased with all he has seen on the way.

It is proposed in future letters to give you the history and workings in detail of some of the mines in these districts about which very little is known. At the East and abroad there is no proper conception of the magnitude of mining operations here, nor of the undeveloped wealth which only awaits the judicious investment of capital. Hence there is a large and open field for work.

Virginia City, Nev., May 1st, 1876.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANES.]

(Continued from last week.)

Diamonds are valued according to their weight, purity of color, freedom from defects, etc. Much depends also on the state of the country where they are for sale. When times are prosperous and money plenty they will find a readier sale than when the reverse is the case. There is no rule which gives the absolute value of first-class diamonds. But the trade is governed to a great extent by the formula devised by Jeffries, to whose work I have before alluded.

His tables assume that diamonds increase in value proportionally to their increase in size. At the time his tables were calculated it was assumed that rough diamonds, both good and bad, averaged \$10 (£2) per carat. (1 carat = 4 grains).

To ascertain the value of any rough diamond he multiplied the square of its weight by the value of one carat. Thus, if a rough diamond weighed five carats, its weight would be $5 \times 5 \times \$10 = \250 .

A cut stone was calculated differently. It was taken for granted that a rough diamond loses half its weight in cutting, therefore the calculation was made on the value of a rough stone of double the weight; for example: for a cut stone of five carats, $10 \times 10 \times \$10 = \$1,000$, and to this price was added the cost of cutting.

The value of diamonds has largely increased since that time (1750), and in 1865 a diamond of five carats was worth in London £350, or \$1,750, reckoning the pound at \$5. The same authority from which I take this valuation says that the stone must be free from the faintest tinge of color of any sort, from any flaw, speck, marks or fissures in any sort, must be bright and lively and free from what is technically called "milk" or "salt." The stone must also be cut in perfect proportion, according to the rules before given. This author also says that it is impossible to calculate the value of a stone above five carats, as the price depends wholly upon the supply and demand.

When a diamond has a decided color it is called a fancy stone, and will bring a very high price.

Unfortunately, the temptation to produce large-surfaced stones at the expense of the rules of true proportion is so great that perfectly cut stones are seldom seen. To own a perfect diamond is to possess a gem in a double sense.

[To be Continued.]

The general appropriation bill, as passed by the House Friday, contains a provision that assays for private parties shall be made by the mints, at prices to be prescribed by the Secretary of the Treasury, and that the fees shall be turned over to the Government.

The public schools of this city held their annual picnic on Mayday.

Our Centennial Views.—No. 1.

We are pleased to announce to our readers that we are ready to begin our Centennial campaign, and can promise condensed reports of all interesting characteristics of the grand exhibition as they are developed during the summer. Our senior editor, Mr. W. B. Ewer, is now on his way to Philadelphia, where he will remain for some time, and furnish us with everything of interest. It is our intention to pay more particular attention to all metallurgical and mechanical improvements that may be useful on this coast, and Mr. Ewer's experience of the necessities in this line will lead him to select for description those which would be most appreciated here. He will give us everything in a condensed form, and procure for us drawings and engravings of such things as merit particular attention. If any of our readers desire further information of such things as they see mentioned elsewhere, we shall be pleased to communicate their desires to our senior, who will endeavor to gratify their curiosity as far as possible. Our readers can

Japanese display. The judges' pavilion commands the interspace between the main and machinery buildings. The music pavilion intersects Belmont avenue, which leads obliquely through the grounds beyond the lake. In different directions the walls of the American, French and other restaurants are visible, and the pavilions and cottages to be occupied by the commissioners and agents of Germany, Sweden, Turkey, Morocco and other foreign countries, and by those of Pennsylvania, Ohio, New Jersey, Indiana, Illinois, Missouri, Kansas and other domestic States, are in all stages of erection in different parts of the enclosure. From 150 to 200 separate structures will cover altogether some 75 acres.

Upon the highest ground in Fairmount park, a short distance north of the enclosure round the exhibition grounds, there has been erected an observatory 150 feet high. From this the view of the grounds, the city and its environs will be uninterrupted, even by the tallest primeval trees that beautify the banks of the Schuylkill.

The plan of the grounds embraces seven miles of roads and foot paths, bridges across shaded and precipitous ravines, summer houses, and numerous fountains fed by water

NEW ASSAY OFFICE AND CHEMICAL LABORATORY.—Price, the well known chemist and assayer, many years connected with the San Francisco assaying and refining works, has fitted up the old Pacific Mail building, 524 Sacramento street, corner of Leidesdorff, as an assay office and chemical laboratory. The interior of the building has been entirely remodeled to suit the present requirements. On the right hand on entering is the main office, with counters, safe, bullion scales, desks, etc. On the left, and enclosed from the main room, is the assay office. This is very neatly fitted up. It contains a ducing and two cupel furnaces and all the requisite fittings for a first-class assay department. Next to this is Professor Price's private office. In the rear of the main office is a sampling room, with apparatus for crushing ore for sampling, etc. Next to this is the melting room, in which there are four furnaces and all needful conveniences. The laboratory for analysis, etc., is up stairs. All the rooms are light and airy, and fitted up with all the modern appliances in the best and most substantial manner. Professor Price is pre-

Dom Pedro in the "Press" Office.

Every one concedes that Dom Pedro d'Alemtara, the Brazilian emperor, who recently paid our city a visit, is conducting himself in a manly, straightforward manner. His entire freedom from display, his plain unassuming style of traveling and mingling with our people, has created a feeling of friendship and good will towards him and his country that will do much towards removing our prejudice against royalty and the countries that are ruled by crowned heads. While in this city Dom Pedro exhibited a praiseworthy interest in mechanical novelties and new inventions. He even took the trouble to visit the Scientific Press Patent Agency, to examine an invention for which we are securing a patent for the inventor. Indeed his interest was so great that he even spent some two hours in trying to find the inventor, Mr. R. H. H. Hunt, in order to have him present to explain the invention, driving in his search to Mr. Hunt's residence on Twentieth street and then back again to our office. The Emperor readily comprehended the ideas involved in the invention, although its details

FAIRMOUNT PARK AND THE CENTENNIAL BUILDINGS.

rest assured that we will furnish much material of interest concerning new mechanical appliances, with illustrations when necessary.

We begin our Centennial articles this week with an illustration giving a view of the whole field, the location of the buildings and methods and avenues of approach. By keeping this plan for future reference our readers can very easily follow our glances from place to place and realize better the scenes which we will describe for them.

In front of the machinery building is a lake, in the center of which appears a future fountain. Other lakes and ponds gleam here and there in the sunlight. Beyond the lake, a little to the left, is the United States Government building, picturesque from the distance. Farther off, to the right, the horticultural building shows its graceful outlines and bright colors. Midway between it and the Government building, is the women's pavilion, over the turrets of which, towards the remotest angle of the grounds, the tinny roof of the agricultural building turns like a shield the blinding lances of the sun. Away to the left, toward the famous Belmont drive, the buildings constructed by the British commission are situated, and a little further on a dark cordon of sight-seers surrounds the Japanese workmen in native costumes at their task of putting up the strictly Japanese buildings which are to accommodate the Japanese officials and a certain part of the

supply equal to that at Versailles. The George's hill reservoir, just outside the enclosure, contains 40,000,000 gallons; but in addition to this source the grivir, which leaves the northern rim of the exhibition grounds, will supply through pumping engines 6,000,000 gallons more a day. Not only the fountains, but the boilers of the steam engines in the main building, the machinery building and agricultural hall, are thus to have plenty of water; and the mains and drains, complete for all emergencies, will be thoroughly drenched and purified.

HARBOR OF REFUGE ON THE PACIFIC COAST.—Luttrell says the proposition for which he secured the sanction of the House to-day to obtain a survey by the Engineer Department of Mendocino, Trinidad, Humboldt and Crescent City harbors, with a view to reporting the best location and probable cost of breakwater and harbor of refuge, was defeated in the House Committee by Piper, but that the present action is just as efficacious as the enactment of his provision in the river and harbor bill would have been.

SEVERAL of the coal leads of the Pnyallup mines have been recently opened, and an expert has been sent for to come from the East to make a thorough examination and test of the mines and coal.

pared to make assays of metals and ores as well as complete a practical analysis of all minerals, salts, waters, or other substances. Particular attention will be paid to the chemical department. There is a complete analytical laboratory in addition to the assaying and bullion rooms. Bars are received for melting, and the refining will be attended to. Eventually a complete gold and silver refinery will be added. Professor Price has been long and favorably known to the public as a thorough chemist and metallurgist, and will, no doubt, get his fair share of business. He has everything arranged at his new laboratory after his own designs, and no expense has been spared in procuring the necessary appliances or in the arrangement of the building.

THE COMSTOCK LONE.—We shall soon publish, perhaps in our next number, an illustrated article on the Comstock lode, showing the manner in which the rich ore is distributed in the vein, and presenting a theory in reference to its pay shutes, with suggestions of rules to be observed in prospecting. The matter is one of interest to mining engineers, mine owners, financiers and speculators.

MESSENGERS, GEORGE S. DONOE, Josiah Earl, W. W. McCoy, Josiah Belden and F. MacCrellish have been appointed the Executive Committee for the Pacific Coast Centennial Committee.

were very complicated and required a special knowledge of one of our leading industries to enable him to comprehend its new features. Altogether we look upon Dom Pedro as a model emperor, and wish they were all of his stamp.

ACADEMY OF SCIENCES.—A large number of interesting donations to the museum of the Academy were received at the last meeting, among them a great many minerals. W. N. Lookington read a paper describing a new species of snake, and another describing a new species of crustacean. W. G. W. Harford also described a new species of crustacean. Professor Davidson read a short paper, by permission of the Superintendent of the U. S. Coast Survey, on the telegraphic determination of the latitude and longitude of San Francisco and Seattle, showing the delicacy and accuracy of the operation. He also read a second paper on "Irrigation in British India," describing and criticising in detail the canals of the Ganges, and its tributary, the Jumna; with their levees, dams, locks, sluices, falls, currents, aqueducts, and distributaries. The paper was strictly confined to the scientific engineering features and principles of the works described, and several errors of the British engineers were pointed out, while their works in general were credited with great boldness and originality.

The Pancake Coal Mine.

During the past few months a large amount of work has been performed at the above mine, in order to place it in better working condition. A double compartment shaft is being sunk and is now down a distance of 215 feet, thoroughly timbered. The sinking of the shaft will be continued. A seam of coal has been already cut and it has been fully demonstrated that sufficient coal upon this level can be extracted to go a great way toward supplying the Eureka market. The pumps and machinery need at the mine are all in fine order. A temporary delay is now being suffered, awaiting the arrival of an additional holler now on the way to the mine, but owing to the bad condition of the roads the transportation proceeds slowly. The mine will be in full blast in two or three weeks, and the shipping of the coal to this place will, in all probability, commence next June. Should the coal answer the purpose, and it promises so to do, a large amount will be required for use at the Richmond smelting works, for the refinery department, and this, added to the demand that will arise from other sources, will give the coal a ready market. The parties owning the mine have labored energetically for years to develop their property, and at a great expense have now succeeded in carrying out their undertaking. We hope that they will yet have a bonanza of black diamonds that will amply repay them for their years of labor and expense incurred in bringing the mine to its present condition.—Eureka Sentinel.

BOYISH DESTRUCTIVENESS UTILIZED.—A recent report of the French *Société Central d'Agriculture et d'Horticulture* states that for some years past one of the principal objects of the society has been to encourage the destruction of injurious animals, particularly insects, and the protection of insectivorous birds. The principals of several schools have seconded these efforts in a most praiseworthy manner. Schoolboys, as a rule, are rather destructive, and advantage is taken of this disposition to kill something. Prizes are offered for the destruction of vermin of all sorts, and at the same time for the preservation of useful birds. Eleven schoolboys in one school destroyed each 1,666 insects, of various sorts, besides 42 nests of caterpillars; and they protected 27 nests of useful birds, sheltering 143 young. This is only one of several cases reported, the numbers of which are mostly much higher. It would appear that insectivorous birds have been almost exterminated in some parts of France, and injurious insects have increased proportionately, so that they have become a formidable scourge.

THE TURBINE.

Simplest, Cheapest,
and Most Durable.

The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL
IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of this remains the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.

Territory for sale outside of California, at reasonable rates and easy terms.

Mills built to order of the best material, and at the shortest notice, by Kimball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.

For further information regarding Mills or Territory, send for New Circular. Address,

A. H. SOUTHWICK,

P. O. Box 1385, San Francisco or

P. O. Box 25, Oakland, Cal.

THE O'HARRA
CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulfurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....\$12.00
Two firemen at \$4.....8.00
15 lbs of salt at 15c.....2.25
Wear of shoes and power.....1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.93 1/3

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

NEW ASSAY OFFICE.

Thomas Price (formerly of the San Francisco Assaying and Refining Works), having fitted up the old Pacific Mail building, No. 524 Sacramento street, corner of Leidesdorff, as an Assay Office and Chemical Laboratory, is now prepared to make assays of the precious and useful metals and their ores, as well as complete or partial analyses of all minerals, salts, waters or other substances that may be desired.

His office will be opened for business on Monday, May 1st, and he hopes that his long residence and experience in his profession will entitle him to a reasonable portion of the business of his friends and the public generally.

PASO ROBLES, CAL., October 18th, 1875.

DEWEY & Co.—Gents: The letters patent for the Tiro Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks.

Yours Respectfully, JOHN H. MERTZ.

Machinery.

The Ingersoll Rock-Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS.

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and HAS AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience,
collected in Europe and America, well acquainted with
correct management of mines and mills, practised in
projecting and constructing mining and milling ma-
chinery, and especially machinery for mechanical ore
concentration, is open for re-engagement, and would
prefer the task of constructing works for mechanical
concentration of low grade ores on a well developed
mine, or of remodeling ineffective works in the ore
milling line for successful operation. Apply to
Messrs. DEWEY & CO., of this office, for reference.

NOTICE.

A Quartz Mine and Mill For Sale.

The Mill containing one five stamp battery, free
water power. Sample of rock from the Mine can be
seen at the Mining and Scientific Press office, San
Francisco. Location: Oregon Gulch, near Oroville,
Butte county, Cal.

About thirty or forty tons of Quartz are already ont
and every day am taking out more.

N. B.—Also manufacturer of Hooker's Deep Well and Double-Acting Force Pump. Received the Silver Medal awarded at the last Mechanics' Fair in San Francisco.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent me at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

AUTOMATIC PUMP.

Raises water by compressed air to any height or distance. Windmill can be set at any distance from the well or spring if required to get a good exposure to the wind.

SEND FOR CIRCULAR.

SEWING MACHINES.—We have a first-class machine we wish to dispose of on favorable terms. Apply at this office.

OAKLAND, Saturday, May 13th, 1876
WOODWARD & TAGGART,

Real Estate Auctioneers.

H. A. OOB, AUCTIONEER, WILL SELL AT
PUBLIC AUCTION.

On Saturday, May 13th, 1876, at Salesroom, 460 and 462
Eighth Street, Oakland.

42 Choice Residence Lots,
THE PROPERTY OF CHRISTIAN BAGGE.

This property is situated in a portion of the city that is improving as rapidly as any part of the city; is but a short distance from schools and churches; but four blocks from the Berkeley railroad, which is now being built and will be completed within 30 days. A station is to be built at the foot of Fourteenth street, which will bring this property within 30 minutes of San Francisco. There is not to be found within the city limits more desirable residence sites than this property presents. A horse railroad will soon be built in front of this property, which will bring it within five minutes' ride of Broadway station. Terms, one-fifth cash, one-fifth in one year, one-fifth in two years, one-fifth in three years, one-fifth in four years. Interest on deferred payment at the rate of 10 per cent. per annum. For further particulars, apply to

WOODWARD & TAGGART, 460 and 462
Eighth Street, Oakland.
MAURICE DORE & CO. 326 Pine Street,
San Francisco.

PURCHASERS please say advertised in Scientific Press.

(Continued from page 294.)

CHERRY CREEK DISTRICT.

MINING.—White Pine News, April 29: Joe Potts, from Cherry creek, paid an evening visit yesterday. He is on his way to Eureka to take the foremanship of the Richmond company's mine. Joe is a pioneer White Pine miner, and we have no doubt will give entire satisfaction to his new employers. He gives very flattering information of the mines in and about Cherry creek, and says the time is not far distant when that district will give a good account of itself as a large bullion producer. At present there are about 100 men employed in the different mines, and two mills are kept constantly employed in crushing the ore taken out. In our next issue we will give full particulars of the mining interest at Cherry creek.

EUREKA DISTRICT.

THE RICHMOND COMPANY.—Eureka Sentinel, April 28: We are reliably informed that the Richmond company will resume active operations at the mine on the left proximo. A number of men are already at work underground preparing for the extraction of ore, and as there is a considerable amount at the dump, hauling to the furnace will be resumed at the same time that operations are commenced in the mine. The repairs at the smelting works have not yet been completed, but we presume they will start up at an early period. No trouble is anticipated between the company and the Miners' union. Joe Potts, an experienced miner, formerly foreman for the Eberhardt company, in White Pine, has been engaged as foreman, and will commence the duties of that position next Monday.

WHITE PINE DISTRICT.

GETTING TO WORK.—White Pine News, April 29: During the week we have seen several parties purchasing outfits for a start to the mines. The deep snow having disappeared in many places, the miners will now be able to pack their tools and provisions into the mountains, and start in for a summer's work. The chances for getting to work this season are at least a month earlier than we supposed they would be a month ago, when from three to five feet of snow covered the whole face of the country.

SMELTING.—Harry Strout is making his arrangements to start up smelting at the Metcalf furnace about the 1st of June. He informs us that the amount of ore now out on the dumps is much larger than at this time last spring. We hope he may be successful in his new undertaking, and can see no good reason why he should not be, for all the necessary appliances to successful smelting are here.

Arizona.

POLAND MINE.—Arizona Miner, April 21: Messrs. Roberts and Poland were in town Monday and Tuesday and left with specimens of the ore which they are taking from the Poland mine, some four or five miles above Hitchcock's, on Big Bug. The ore is not of the highest grade, nevertheless gold and silver are both visible to the naked eye, but the value is satisfied if they attach to it consists in the fact that they know the ore to contain mineral in paying quantities and that it is of enormous size and extent, and with walls as plainly defined as those of a plastered house. They have out some 200 tons of smelting ore, and it is their intention as soon as they prove it to a sufficient depth to be absolutely certain that it is inexhaustible to erect reduction works on the site. So far, the value of the mine is Mr. J. M. Roberts that he bought an extension of Mr. Hitchcock on Monday, paying \$500 for it without any development whatever.

Idaho.

ON A PROSPECTING TOUR.—Idaho Avalanche, April 22: Charles Tregakis, George Hammell and Bill Hoffager left this morning for Alturas, and expect to be absent for several months. After reaching Rocky Bar they will strike off into Wood River district, which has never been very closely explored, and spend some time in prospecting for the rich mines that are known to have an existence in that vicinity. Their field of operations for the summer will be in the northern section of the Territory. They have a vast field before them and will traverse a country that must within 20 years become one of the most prolific and promising regions on the Pacific slope.

To know how far the spirit of obstruction is developing itself, we understand that some parties holding claims against the mines are not only demanding full payment of the amounts, but insisting that interest shall be added, commencing with the time they left off work. Truly, the fools and lunatics are not all dead yet.

EARLY THIS AFTERNOON we learned that all or nearly all the outstanding liens on the Illinois Central and Mahogany mines have been heard from and the holders have come out like "little men," determined to surrender them in support of what seems like the most feasible proposition for getting at least a portion of their dues.

ON SATURDAY evening Mr. Wilson, superintendent of the Silver Cord mine, received a telegram from Martin Jones, President of the Silver Cord mining company, in San Francisco, to the effect that owing to the existing condition of affairs, his (Mr. W.'s) services were no longer needed in the capacity of superintendent. This looks as though the companies below were resolved to have no recognized agents in this camp at present, the reason for which, taken in connection with the approach of the term of the district court and the prospect of lien holders' suits, are quite apparent. Further interesting developments may soon be expected.

A LABOR insurrection of those interested in the mining claims here seems to manifest a commendably liberal spirit in coming to the front and making such sacrifices as the emergency demands. Many of them have even offered to surrender claims amounting to several hundred dollars for the benefit of those who still seem to be in doubt about the justice and propriety of accepting the Graham proposition. Such sacrifices are worthy of all praise. Those who make them see that the salvation of the camp depends upon the immediate resumption of work.

Utah.

WEST MOUNTAIN DISTRICT.—Cor. Salt Lake Tribune, April 27: In company with Henry M. May, one of the fortunate owners of the Yosemite mine, we visited that section of West Mountain district, overlooking the valley. In the Yosemite mine the main incline, through which the mine is worked, is down over 400 feet on the ledge, and although worked to the line east and continuing down the line and the prospect of silver—purchased lately—on the west, it has not even "pinched," showing well defined walls in all the workings.

A. G. REMS took us through the new workings of the Winnamuck. The perpendicular shaft is down 240 feet. At the bottom is a pump of a new pattern, which works well, but not powerful enough to master the increasing quantity of water. They are now sinking on the foot wall on an incline, and are down about 30 feet below the bottom of the main shaft. We felt like praying one time when on the cage going down; but knowing that Mr. Etchel manipulated the engine, we concluded to postpone that pious undertaking for another time. This mine, like the Nez Perces, works eight hour shifts. Why it is that mine owners do not adopt this system generally, is surprising.

PATENTS & INVENTIONS.**A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.**

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., May 2d, 1876.

FOR WEEK ENDING APRIL 18TH, 1876.*

ROPE GRIPPING DEVICES FOR PROPELLING VEHICLES.—Asa E. Hovey, S. F., Cal.

HOSE COUPLINGS.—George W. Price, S. F., Cal.

TICKET HOLDERS.—William U. Bohm, S. F., Cal.

ORE FEEDERS.—Thomas A. Cochrane and Joshua Hendy, S. F., Cal.

GATE LATCHES.—Henry Jones, Shastu, Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

WATER WHEEL.—Moses M. Staples, San Francisco. This invention relates to certain improvements in that class of water wheels which are intended to rotate by the centrifugal force of a stream of water under a considerable head, escaping from the periphery of the wheel. It consists in a novel method of constructing the wheel so that the inventor is enabled to make and set it up at places where it would be difficult to transport a complete wheel, and he can also repair or replace the wheel at any time at a small expense. It also consists in a means for regulating the size of the discharge opening so as to proportion it to the amount of water supplied, and keep the wheel full. This wheel may be used with good effect also in driving small machinery, as lathes, sewing machines, etc., by the use of small streams of water having a considerable head.

WINNOM SASH STOP.—W. A. Hawthorn, Carson City, Nevada. This is an improvement on sash fastenings, consisting in the use of a screw and bearing plate, which are attached to the sash, and are capable of being so operated as to secure the sash at any point. Through the side of this sash the inventor makes a hole into which a screw turns. A spring or plate is secured to the edge of this sash, which lies next to the casing, and the point of the screw presses against this plate, one end of which is free. By turning the screw the plate is pressed outward and, presenting a considerable surface, is caused to bind and hold the sash firmly at any point. The plate also prevents any marring of the wood, as might occur if the screw only were used. To secure the sashes firmly when closed, an inclined slot is cut into the side of the casing, and when the sash is closed the plate will be forced into this slot by turning the screw, thus securely locking the sash so that it cannot be opened from the outside. The screw may be provided with a thumb piece, or may have a slot for a screw driver across its head, or he provided with a key shank sunk into the wood so as to be more secure.

LAND GAUGE FOR PLOWS.—E. C. Brown, Antelope, Yolo county. This improvement is called a "lever gauge," by means of which the inventor is able to change the line of draft so as to give the plow more or less land, as required, without stopping the plow. It is seldom that a piece of land of any great extent possesses a surface soil of uniform character. Some places are harder and less easily penetrated by the plow than the others, especially where the land is uneven, so that a plow that is set to turn a furrow of a stated width will at places almost stall the team, while at other places it will run easily. The object of this improvement is to place in the hands of the plowman, whether he is operating a sulky or a common handle plow, a means of regulating the width of the land which the plow turns without having to stop the team, thus regulating the draft upon the team without varying the depth of the furrow. The invention cannot well be described in detail without the aid of engravings. It improves this class of plows, however, as the driver can, by shifting the lever to the right or left, change the landing of the plow without trouble.

TUBULAR CHIMNEYS.—Jeremiah Browell, San Francisco. This invention relates to certain improvements in the construction of chimneys or flues, which are made in sections, and it consists first in constructing the flue or chimney of stone, cement, clay or earthenware tubular blocks or sections, which are perforated longi-

tudinally for the reception of binding rods, and have their ends so formed as to be united in a smoke or gas tight joint. The patent further consists in the formation in these blocks of a series of ventilating flues by which the chimney may be kept cool, or the air which is introduced from the outside may be heated and conveyed to the apartments of the house to heat them if desired. In order to prevent the blocks constituting the chimneys from becoming spread, rings are employed at each of the joints through which the upright rods pass (as described in Mr. Browell's former patent), and the hole is thus bound together and made solid and steady, while of sufficient tightness to be built upwards from any floor without extra support from below. The rings may have projecting extensions to serve as supports, being fastened to beams or cross pieces near the line of the chimney. The flues described will be of special value in kilns, potteries, etc., as the heat from them may be utilized to dry the manufactured articles before they are baked.

COAL RESERVOIR, SCREEN AND SHUTE.—B. C. Satterfield, C. L. Crisman and Jas. McKinley, San Francisco. The patent comprises certain improvements in devices for screening coal, principally when it is discharged from a ship upon a wharf, so that it can be at once assorted and received into vehicles to be carried to its destination. The improvements consist in the formation of a general reservoir, having gates in the bottom, so that the coal may be allowed to fall upon the screens at the time when the carts are ready to receive it and it will thus be perfectly screened, which is not the case when, as in the present machines, it is dumped directly upon the screens and allowed to accumulate there, thus making a reservoir of them. The inventors employ two or more screens and shutes, leading in different directions from the reservoir, so that a number of carts can be loaded at once. A frame of suitable height is used, upon the top of which is a large hopper-shaped reservoir, having at its bottom two or three gates or doors, which may be moved by any suitable mechanism. Below each of these gates a screen and shute is placed, each one leading down at an incline to a point where the carts can be driven up to receive the load. It will be seen that no coal is admitted upon the screens until the cart is ready for it, and thus there is no accumulation of coal which might slide down without being screened at all. A shute without a screen may be used when it is not necessary to separate the coal.

MOVABLE TYPE.—Wm. H. Bell, San Francisco. The improvement in this patent is more especially applicable to that class of rubber or elastic types which are intended for hand use in printing and marking prices upon different articles. It consists in constructing each type with a back which will fit the next type upon either side, and preserve a row of them in line; and in the combination with these of a grooved holder, within which a line of the type may be held for continuous use. This construction gives a convenient and rapid mode of using movable hand type for marking prices of articles, or for other purposes.

WINDMILLS.—John Brower, D. Reed and J. C. Reed, Colusa. This invention relates to certain improvements in that class of windmills which are made adjustable by means of vanes or sails, which can be turned about an axis so as to throw them more or less out of the wind, and it consists in a series of radial arms, which are connected with the vane sections by suitable rods. These radial arms are mounted upon the end of a shaft which passes through the main shaft and has a motion longitudinally, so that it is drawn forward when the wind throws the vane back, and a weight or spring draws it back as the force of the wind decreases.

THE WILLAMETTE WOOLLEN MILLS BURNED.—On Wednesday morning last a fire broke out in the main building of the Willamette woolen manufacturing company's mills, Salem, Oregon, and owing to the building being thoroughly saturated with grease and oil, from long usage, the fire made such rapid headway that before the fire department reached the spot the entire main building was completely wrapped in flames. The buildings comprised the wool house, dry house, office and the main building in which was situated the machinery, each of them being very large and of the best class. They were all destroyed in an incredibly short space of time, and the heat at times was so intense as to prevent the firemen from working to advantage. The loss of the mill, which was one of the most extensive on the coast, is considered a public calamity for Salem, throwing one hundred and eleven men, boys and girls out of employment. No Chinese have ever been employed. The total loss will reach \$150,000; insured for about \$67,500 on the buildings, machinery, wool and goods in process of manufacture.

FIRE AT EMPIRE FOUNDRY.—Last Saturday night a fire was discovered in the pattern shop owned by Dunn & McCune, connected with Savage & Son's Foundry, on Fremont street. The origin is supposed to have been sparks falling on the roof. The fire was speedily extinguished by the department. The loss will be less than a thousand dollars, and is covered by insurance.

General News Items.

COMMODORE VANDARBILT is seriously ill. THE public debt was reduced \$2,780,000 in April.

GENERAL McDOWELL is on his way to California.

A YOUNG lady of this city, disappointed in love, committed suicide last week.

MARK TWAIN appeared successfully on the stage in the "Loan of a Lover," in Hartford, Wednesday.

A SPECIAL from Paris to the New York Herald says Boss Tweed is in the gay French capital.

THE Centennial exhibition will be formally opened to the public Wednesday, May 10th, at noon.

THE revenue officers of this city made a descent on "crooked" whisky houses and distillers on Monday last.

It is considered probable that the Oxford university boat crew will compete in the Philadelphia Centennial regatta.

THE Oregon wagon road company's bill makes slow progress in Congress, there being a strong disinclination to authorize an issue of more land scrip.

SEVERAL bodies of workmen in Paris have asked permission of the Government to open subscriptions for the purpose of sending some of their number to the Centennial exhibition at Philadelphia.

THE citizens of Antioch drove out the Chinese from their town last Monday by ordering them to leave by three o'clock. That night the houses in the Chinese quarter were all destroyed by fire.

THE Presidents of the six Chinese companies have promised Mayor Bryant that if the city would give them a lot they would probably erect a house for those Chinese who are suffering from leprosy and contagious diseases.

SENATOR SARGENT is confident that, in regard to the Chinese question, by the thorough presentation of the subject which he proposes to make to the Senate, all important action as part of the treaty-making power can be secured to accomplish the desired result.

THE House has sustained the action of the Committee on Appropriations in the general and heavy reduction of salaries and employees in every department of the Government, and it is thought the service will be crippled in some cases in consequence, if the bill passes in that shape.

THE House Committee on Appropriations has begun consideration of the Indian appropriation bill. The appropriation last year was nearly \$7,000,000. A very large reduction will be made this year. The reduction is made possible without affecting the efficiency of the Indian service.

ABOUT 2 A. M. Tuesday about ten masked men appeared at the coal mines north of Massillon, Ohio, seized and tied the watchman and set fire to the coal shafts. The Willow Bank mine, Mount Bank mine and Rhodes Company mines are now burning. The fire department of Massillon have gone to the scene of the fire.

THE Committee on Public Lands will soon begin the discussion of the important question in relation to the surveying of public lands. Thousands of dollars have been stolen by dishonest surveyors, and the entire system needs renovating. It is believed that a plan of surveying from monuments established at given points will be adopted.

DESTRUCTIVE FIRE AT POCHE.—About three o'clock Wednesday morning a fire broke out in an unoccupied building. It spread in either direction till a whole block, from Staples' furniture store to Beaupre's brick block, was in flames. It communicated to the west side of Main street, destroying all the buildings between Beaupre's block and Hughes' blacksmith shop. In all, about twenty-five buildings were destroyed. With the exception of the Daily Journal office and Mrs. Hickox's millinery establishment, the houses burned were residences.

THE MINING DETRIMENT QUESTION.—The California Legislature memorial respecting mining detritus has been presented and referred in both branches of Congress to the Committee on Commerce, but the members of the delegation are at a loss what remedy to propose for the difficulty, except the preliminary recommendation necessary for an investigation and report on the subject by the Government engineers.

DURING a recent visit to Sacramento it seemed more pleasant than usual to us in the capital city. Considerable improvement is going on, and business in most branches seemed prosperous and hopeful for the future. We visited the "Holly water works" machinery. "The plant" works well and is a powerful aid to the fire department. Some such system for protection against fire should be adopted in Oakland and other cities in our dry California climate.

WE SHALL SOON publish an illustrated description of the O'Hara chloridizing furnace, of which present information can be had by reference to our advertising columns.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

WOOD AND STRAW BURNING ENGINES.

At prices most economical to customers, at the **SACRAMENTO GLOVE FACTORY OF I. W. Luck**, Tenth St., between J and K Sts., Sacramento. None but the best quality of California tanned skins used. Ladies' and men's colored plain and Indian dressed. Fine and common gloves and mittens on hand, or made to order on short notice. **Send your size or number and you can order by mail. Satisfaction guaranteed.** Ladies, farmers, miners, engineers, and all requiring serviceable gloves are invited to call at the factory.

Columbia District.

A correspondent of the (Nevada) *Silver State* writes from Varyville as follows: Spring has made its appearance, and with it comes a little activity among the prospectors and miners of this district. There has been a

Heavy Fall of Snow

In the mountains in this part of the county this winter, consequently there will be much more water than there was last season; although there has never been a season known but what there has been sufficient water for all mining purposes in this district, and very few mining districts are as much favored as Columbia in regard to water. We have four large running streams in this district that furnish an abundance of power to run all the mills that would be required to crush millions of tons of ore.

The Florence Mill

Has just cleaned up a 50 ton run from the Badger, and obtained a 45 ounce brick, worth \$18.50 per ounce. The entire cost of mining, hauling and milling was \$210, and the mine shows a very large amount of ore of the same quality. Mr. Grant has milled ten tons of ore from his Snow Creek ledge, and it worked very satisfactory. Grant & Co. discovered a short time since a large gold ledge upon the divide southeast of Pine Forest six miles. It is from eight to twelve feet wide, and the gold has the same appearance as that found at Silver City, Idaho—\$8 or \$10 gold—but the ledge is very large, and a large amount of the croppings will go up into the hundreds. They intend commencing work upon it as soon as the snow gets off a little more.

The Independent Company

Are hard at work pushing their shaft down. They have a good three-foot vein. The owners of the Central mine are at work taking out 100 tons of ore to have worked in the Florence mill.

The *Russian River Flag* gives a summary of the quicksilver mining of that county, showing good prospects for the future. There are now about 15 claims in operation, though all do not pay a profit.

WALTER C. STALEY has found placer diggings about 15 miles from the San Fernando tunnel, Los Angeles county. The samples sent to town prove to be scale gold of good quality.

ANOTHER vein of sulphur, the richest yet found, has been discovered at Steamboat. Wheeler & Dean are the owners.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

SMITH'S PATENT POWER MORTISERS,

WITH LATE IMPORTANT IMPROVEMENTS.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc., send for our new Illustrated Catalogue. BERRY & PLACE, Selling Agents.

San Francisco.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS, STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made, in simplicity of construction, economical use, of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

Giant Powder.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1,

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2,

For medium and seamy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay, and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

WANTED—A SUPERINTENDENT,

To take charge of a Mining Property. Must be thoroughly familiar and competent, by practical experience, with the leaching of low grade Copper ores in all its details. Apply to

HUHN & LUCKHARDT.

Nevada Metallurgical Works,

21 First street, S. F.

\$5 to \$20 Per Day at home. Terms free. Address G. STINSON & Co., Portland, M.

Manufacturer of perforated sheet metals of every description, at reduced rates. Mill owners using Battery Screens extensively, can contract for large supplies at favorable rates. This is the only establishment on the Coast devoted exclusively to the manufacture of Screens

GOLD, SILVER AND COPPER MINING, Reducing and Concentration Machinery.

Address, FRASER, CHALMERS & CO., Chicago, Ill.

Hoisting Engines, Diamond Pointed Rock Drills, Manufactured by M. C. BULLOCK.

THE MINING AND SCIENTIFIC PRESS is one of the best papers published on this coast. It should be in the hands of every miner and mechanic in the State. The issue of last week contained an excellent article on the old product of this coast.—Oroville Mercury, Jan. 28.

ANGELL'S CHARCOAL DENTAL SOAP for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco.

MINING MACHINERY DEPOT,

PARKE & LACY, 417 Market Street, S. F.

SOLE AGENTS FOR

Burleigh Air Compressors,

ROCK DRILLS and

Tunneling Machinery.

HASKINS'

ENGINES AND BOILERS,

WRIGHT'S

Bucket-Plunger Steam Pump.

COSMOPOLITAN EMERY

WHEELS AND STANDS.

HASKINS' PORTABLE HOISTING ENGINES, constructed especially for economical use in mining districts, with Compressed Air or Steam, adapted to all classes of underground work and made throughout on the interchangeable plan, so that all parts can be duplicated when desired. Catalogues and Estimates given on application.

Putnam Machine Company's

MACHINISTS' TOOLS and

Wood Working Machinery.

HEALDS & SISCO

Centrifugal Steam Pumps.

FARMER'S ELECTRIC MACHINE
FOR BLASTING AND HILL'S
EXPLODERS.

HASKINS' BLOWING ENGINES

For Mines.

Large Assortment of

MORSE TWIST DRILLS.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING

THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS

ON THE LEGS OF TRIPOD, ARE ALL IMPROVED

AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never fails of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

Volatility of Gold and Silver.

[By ALMARIN B. PAUL.]

As more attention than heretofore is being given to the roasting and calcining of ores, and as questions relative to the volatility of gold and silver have been so often asked, I have thought some data on the subject might be interesting to your readers.

In the minds of many, the idea that gold and silver can be passed off as a vapor is regarded as preposterous, and that over \$100,000 could go "up the chimney" of our San Francisco mint was hooted at, but when the sweeping of roofs in the vicinity all around showed gold, the question naturally came up as to where it came from if not the mint.

The fact that metals at high temperature do vaporize is so clearly settled by experiment that to doubt is simply exhibiting a lack of knowledge upon the subject. It has been conclusively shown that gold melted at the temperature of an ordinary furnace suffers some loss, and the more volatile are the metals with which it is associated, the greater is the percentage.

Silver suffers more than gold, and often to a very serious extent. In one experiment I made where silver was associated with lead, arsenic and antimony, over one-half the value passed off in vapor.

Some years ago, in Utah, at one of the furnaces quite an excitement was brought about in consequence of so serious a loss that the employees were charged with embezzlement, but all protesting against the charge and giving it as their opinion that it passed off as vapor, an investigation was instituted, which resulted in determining this to be the fact. Exactly what was the loss I do not remember, but it was very large. This discovery was the result of careful assays as to the value of ores before submitting them to the furnace and seeing the results afterwards.

Every one who has worked reverberatory furnaces know that the roofs of them become coated with the smoke of gold (if I may be allowed to use such an expression), especially in the roasting of sulphurets. The amount of gold carried off is not known—our mining men generally accepting Shakespeare's motto: "He who knoweth not what is lost loses nothing." Bricks of these furnaces, to a given distance, become saturated with this vaporized gold.

In chloridizing silver ores there is in part an arrest, in consequence of a change of conditions; still a certain loss is inevitable, especially if antimony or arsenic is present. And what this loss is our miners have given but little attention to ascertaining. All the Mexican vases show silver at the crown of their chimneys, and in no small quantities after a long run. But I will drop our home experiments and facts, as they may not have the same weight as views of men higher in rank than your humble servant.

St. Clair Deville showed by his experiments that with the oxyhydrogen blast he could vaporize gold just as zinc or mercury are distilled.

It was found also "that when gold was melted in the focus of the great Italian burning glass, that it fumed away in vapor, and that a silver ball held in contact with the vapor was palpably gilt." It has also been determined that the purple of an inverted cupel, when used in an assay of gold, is gold.

Napier gave considerable time to the investigation of this subject of vaporization of the precious metals, and his experiments were exhaustive and conclusive. Without going into too lengthy an account of the results of his experiments, I will cite only two. An examination of the flue leading from a furnace to the stack, and a distance of 700 feet, was as follows:

	Lead.	Silver.	
	Oz.	Owt.	Gr.
100 feet distance from furnace, 65 per cent.	61	2	8
200 "	46	2	8
300 "	46	2	17
400 "	64	2	1
500 "	64	3	6
600 "	58	1	12
700 "	62	2	17
Foot of Chimney,	66	3	8

An examination of a chimney showed as follows:

	Top.	Middle.	Bottom.
Metallic Silver.....	29,280	39,169	48,750
Oxide of Silver.....	1,964	3,140	682
Gold.....	2,120	2,600	4,200
Total Grains.....	33,464	44,909	53,632

From the flues of one of the large melting

establishments of Australia it was positively ascertained that for every pound of metal which passed through the process of melting, there was a loss by vaporization of 14,760 grains. The dust from the shaft showed for every pound 29.54 grains of silver, and 14.12 grains of gold, giving a total of 43.66 per pound.

If so much attaches itself, in its ascent, how much must pass off out of the chimney?

Fig. 1. Sectional Side Elevation of Furnace.

All this gold and silver is simply a mist, which cannot be detected by washing or by the eye except with a glass of 100 diameters. I could extend this further, but what is the use? I simply desire to present facts, that our mining men may not build too hot a fire around their hopes, for fear it might end in smoke and pass up the chimney; and to show that the absolute destruction of base metals without a loss of the precious is a demonstrated impossibility.

The chloridizing of silver ores by careful

Fig. 2. Bottom Hearth of 50 Ton Furnace.

manipulation is practically profitable and correct, and the calcining of ores by simple furnaces at a moderate heat in order to dry and to soften the ore, whereby it can be moved cheaply reduced, I have long been an advocate of, and I am glad to see that California quartz miners are beginning to think well of it.

As mining is getting to be a pursuit of some magnitude, all these questions must be considered, investigated and experimented upon,

Fig. 3. The O'Harra Chloridizing Furnace.

and facts should be thrown forth to the public for our mutual good.

The Helena, Montana, Independent claims that by building a railroad from that city to the head of navigation on the Missouri river, freight can be laid down there at less cost than Salt Lake pays for freight, not exceeding two and a quarter cents.

It is asserted that the gold now being exhibited as coming from the Black hills is mostly procured from Montana, Colorado, and other points, to be used for advertising purposes.

The O'Harra Chloridizing Furnace.

We give on this page illustrations of the O'Harra chloridizing furnace, one of which is now in successful operation at the Consolidated Poe mine, in Nevada. Fig. 1 is a sectional side elevation; Fig. 2 a plan or view of bottom hearth; and Fig. 3 a perspective

view of the furnace. We take from the Nevada State Journal the following description of the furnace, together with several important items about this new mode of treating Peavine ore:

"The ore of the Consolidated Poe mine is crushed through a ten stamp dry battery, from whence it is elevated continuously as it discharges from the battery to a large hopper, from which it feeds into the O'Harra Cham-

creases, and is then moved back to the end of the furnace through the flames of the two fires, and after passing the last fire it is still moved and turned over a space of fifteen feet on a cooling hearth and is discharged into the ear cool and ready for the amalgamating process. There are no chemicals used in the ore but chloride of sodium (salt).

"When the ore gets under a low heat the antimony commences to burn the lead, antimony, zinc, iron, copper and other base metals, changes to a sulphate, caused by the superheated steam playing through the flames and oxygen from the atmosphere. When the ore falls to the lower hearth the most of the base metals are oxidized, while the silver remains as a sulphate. Now from five to eight per cent. of salt is fed into the ore from a hopper that discharges about a pound every time the plows pass along. The ore being under an increased heat with the oxygen from the atmosphere mixing with the flames caused by the draft and also superheated steam, causes chemical changes to take place and thereby changes the silver and gold to a chloride. The sulphates decompose; the sulphur, liberated, unites with oxygen and hydrogen, creating sulphuric acid, which attacks the salt, decomposes it and liberates the chlorine gas from the soda; silver, having a strong chemical affinity for chlorine, takes up a portion and is converted into a chloride of silver, which is easily amalgamated when brought in contact with mercury in an iron pan.

"The ore of the Consolidated Poe, and in fact all the ores in the district, are of a very rebellious nature, and have been found very difficult to work, but it is found of late that the O'Harra furnace will work the ore up to 90 per cent. These ores are the most complicated chemical compounds to be found in Nature's laboratory. The ore is from 30 to 90 per cent. metal, with hardly any gangues such as quartz or spar, but in fact is made up of antimony, lead, tin, zinc, cobalt, nickel, iron and copper, with silver and a very little gold and a large per cent. of sulphur and arsenic. The chemical analysis proves it to be argentiferous silver fahl ore, argentiferous gray copper ore, miargyrite, stromeyerite, zinc blende, iron pyrites, sulphide of antimony, and arsenic with sulphurets of silver and silver held in all the other compounds. The ore pays from \$20 up to \$300 per ton. Argentiferous fahl ore is a chemical compound—copper, antimony, arsenic, sulphur, lead, iron, zinc, silver and sometimes gold and quicksilver. Miargyrite is sulphuret of silver and antimony. Stromeyerite is a sulphuret of silver and copper. Zinc blende is a sulphuret of zinc and silver."

The furnace is guaranteed to chloridize from 85 to 95 per cent. of any gold or silver ore that are not more profitable for smelting. It will also desulphurize ores and put them in proper shape for working in cupola furnaces. The cost of roasting and chloridizing by this process is stated at \$2.93 1/2 per ton, and in a furnace of three times the capacity, the cost is decreased twenty per cent. By reference to our advertising columns the details of cost may be noted as well as the address of the inventor.

THE MINERS' STRIKE.—There is much excitement at Massillon, Ohio, over the miners' strike. The green hands are working under the protection of the militia. Two companies of soldiers have been ordered there from Sandosky. The Herald's Massillon special says: Governor Hayes has written to Adjutant-General Wickhoff, expressing fear that the present force at Massillon would prove insufficient should there be any further disturbances in the mining districts. He further instructs him to take every precaution, and to have it thoroughly understood that the militia will remain until the lawlessness is effectually quelled. The Adjutant-General has summoned two more companies, who will arrive to night. The Grand Jury has found numerous indictments against partisans in the recent riots at the Farmington mine, but as yet no arrests have been made.

MR. A. C. KNOX.—We are pleased to say that this gentleman, who has been connected with our office more than ten years, is now on a corresponding and business tour to El Dorado county, with the intention of journeying northward. He has our entire confidence.

At the University.

On a bright day of last week we passed a few hours at the Stats University, on a flying visit to Prof. W. B. Rising, professor of chemistry. With Prof. Rising we made a call upon Prof. Hilgard, with whose name our readers are familiar from his favors to the Press. We took a look through the items of agricultural work which Prof. Hilgard is prosecuting, and we were pleased to notice the spirit of intelligent activity which characterizes his efforts. Of course, as all understand, the late lamented Legislature put the departments of the University on very short commons, and all enterprises are restricted, but there is apparent a commendable disposition to do as much as possible within the legitimate revenues of the University.

Soil Analysis.

In his laboratory Prof. Hilgard is just now doing actual work upon questions submitted to him by the farmers of the State. We printed not long ago an analysis of an alkali soil from Sherman island, furnished by one of our correspondents, and this week we print a report upon another soil specimen from Los Angeles county. We regard this work of especial interest and value. In the absence of a complete survey of the State, from which could be learned the characteristics of the different soils, there is a way open by which the farmer may gain, at the State expense, many useful hints concerning the soil he is cultivating, and that is by applying at the agricultural department of the University.

Prof. Hilgard has had long experience in the analysis of soils and maintains its practical value. He does not advocate the practical value of an ultimate analysis, but claims, as we believe truly, that by determining the available plant food which exists in any soil, taking into account the conditions of situation and mode of tillage, there can be gained a knowledge of what can be profitably added to the soil, which subsequent practice will prove true and trustworthy. We are glad to know that our readers are taking steps to ascertain what use can be made of University science in their operations.

In securing data for determining the physical characteristics of different soils, Prof. Hilgard employs an apparatus in which water is forced through the soil at different pressures. At first the moist minute particles are driven over the top of the receptacle into a receiver, whence they can be taken for weighing. The pressure of water is then increased and the next lightest particles are forced over for weighing, and so on with different pressures until all the particles of soil are separated into their specific classes. The Professor has introduced a most valuable improvement to this apparatus, in the shape of a beater which churns the particles as the water is passing through them, preventing the current from carrying over any flocculent masses and compelling each mechanical division of the sample to wait its pressure which is requisite to send over its class of particles. This apparatus accomplishes in a short time what would otherwise be a most laborious undertaking. We saw a specimen of its work in the separation which had been made of the particles of the Los Angeles alkali soil of which an analysis is given elsewhere this week. At least a dozen divisions of the soil had been made in respect to the size of the particles composing it. Of course this definite knowledge of the physical nature of a soil is invaluable in determining its physical properties, viz.: absorptive, adhesive, retentive and other powers.

Home Made Chemicals.

We were much interested in examining the laboratories to note that apparatus has lately been introduced for producing chemically pure acids and ammonia from the cheap commercial articles. Thus the chief materials for Profs. Rising's and Hilgard's laboratories are secured at but a fraction of the price demanded for pure chemicals by the manufacturers, and in addition to this saving of expense the chemical students gain a better insight into practical chemical manufacture than they could from the smaller distillations of the analytical laboratory.

The Propagating Department.

In the propagating department, which is under the immediate supervision of our contributor, Mr. John Ellis, the horticulturist, we found evidence of very successful work. His plants have been propagated with great care and most successfully, as the green rows of scions testify. He has material enough not only to add greatly to the beauty of the grounds, but also to make valuable tests of useful plants under various conditions; but the work in this useful department will be much restricted because of a lack of funds.

During our visit we found the gentlemen of the agricultural department ready to give us all the information desired concerning the work they have in hand and expressing an earnest desire to do everything in their power to minister to the progress of agriculture in our State. We trust that our readers will not hesitate to test the quality of the agricultural department when any point in their work requires or invites such light as scientific men can cast upon it.

The most deplorable and disgusting feature of the Black hills excitement, says the Denver News, is the efforts of the parties who are coining money out of the folly of the victims of the furore to lure them on by systematic false representations. Cheyenne, Omaha, Sioux City and other outfitting points are especially culpable in this respect.

Mining Suits.

A suit has been brought in the Twelfth district court by Edward C. Lovell *et al* against Thomas Seale, B. B. Minor, H. W. Vaughn, H. W. Sesle and William Jacobs, directors of the "63 gold and silver mining company," for alleged fraudulent mismanagement of a mine owned by the company and in which Lovell and others were shareholders. The plaintiffs allege that Thomas Seale obtained his election as president of the company by fraudulent means and by threatening to deprive one Riley, a former superintendent of the mine and owner of 14,000 shares of stock, of his interest in the mine in case of a refusal, induced him to lend his aid in securing the full control of the company to said Thomas Seale. He then managed the mine, it is alleged, in such a manner as to cause loss to the stockholders, and appropriated money paid into the company on assessments. William Sibley also files a complaint against the same parties, praying for an injunction restraining them from selling 14,000 shares belonging to plaintiff and held by defendants for assessments alleged to have been illegally levied. Plaintiff prays that said directors may be removed and the books and papers of the company turned over to the shareholders.

In the Fourth district court last week the suit of James Smith *et al* against the New England tunnel and smelting company was on trial. This action is to have declared null and void the transfer of 12,000 shares of the capital stock of the company on April 21st, 1876, to J. D. Thompson, of the firm of Stacy, Thompson & Hart, and that such of the defendants as now hold the shares be required to transfer them back to the company. That the defendants, D. K. Tripp, James Morgan, William Stewart, George W. Brown, J. J. Green, A. C. Hammond, John S. Stacy, J. D. Thompson, William H. H. Hart and C. C. Tripp, or either of them, who may hold any stock of the company, in trust for the same, be ordered to transfer the stock back to the company; that the company be ordered not to convey any of its capital stock to any person without the consent of a majority or all of the stockholders; that in the meantime a temporary order of injunction be issued, restraining the defendants from transferring or in any other way disposing of any of the stock of the company which they may hold in trust for the company, and in particular from disposing of 37,000 shares which were purchased by the company at the assessment sale on the 13th of April, 1876, other than a transfer of such stock as the plaintiffs may consent to; also, that the defendant, C. C. Tripp, be enjoined from voting at any and all meetings of the stockholders of the company by means of the transfer of certain stock to himself without authority from the stockholders. The capital stock of the company is \$10,000,000, divided into 100,000 shares of \$100 each. Only 63,000 shares have been subscribed for and are held by bona fide stockholders, which the plaintiffs claim to be.

James G. Fair on the Silver Question.

During James G. Fair's recent visit to the East he was overhauled by the ubiquitous interviewer, and this is what he was made to say:

Reporter.—As you have doubtless given the matter much thought, what are your views as to the future value of silver as it relates to gold?

Mr. Fair.—Silver has declined very considerably; in fact, for a time was unduly depressed, touching as low as 52 pence in London, but has quite recently advanced to 54. I think that there need be no aerious apprehension of further depreciation, and the difference will doubtless continue about as at present, say 16 to 1. While the production is rapidly increasing in this country, that in the rest of the world is falling off. The statistics for 1875 show a decrease in the entire production of over \$11,000,000 as compared with 1874. Silver is a good article to buy on speculation when as low as 53.

Reporter.—From what quarter do you expect a demand sufficient to absorb this immense production of silver?

Mr. Fair.—A somewhat erroneous impression gets abroad about our mines being all silver. It is true they are called "silver mines," while, in fact, the product contains in value from 46 to 50 per cent. of gold. In making our exchanges we get the value of the gold in gold coin, and for the silver we receive gold also: if the market for silver is 53½d we get about \$118½ gold. Our daily transactions on the coast are almost all in silver, and yours soon will be; it will require \$50,000,000 to redeem these little rags [holding up a ten-cent shin-plester], which you people call money. China and Japan, and other countries in that direction, will continue to take a large amount, while some parts of Continental Europe will use it as heretofore. In Austria it is a legal tender, and their Government loans are made payable in silver. The trade dollar, containing 420 grains of pure silver, will go hence, while the standard American dollar, with only 412½, and the halves and quarters, with 387, will enter into general circulation, taking the place, as I before remarked, of these rags. This large production will of itself stimulate the use of it in various ways aside from a circulating medium.

Coinage at the Mint.

There were 1,876,000 pieces coined at the mint in this city last month, of which 1,737,000 were in silver and 139,000 in gold. The descriptions compare as follows with the same month last year:

	1875.	1876.
Double Eagles.....	\$2,560,000	\$2,780,000
Trade Dollars.....	652,000	385,000
Half Dollars.....	229,000	15,000
Quarter Dollars.....		128,000
Dimes.....	17,000	81,000

Totals.....\$3,458,000 \$3,389,000

For the corresponding month of 1874 the amount was \$1,752,000, against \$1,332,000 in 1873. Most of the double eagles made last month were shipped to the East, the total exports of that coin amounting to \$1,859,800. This is the first month in some time that the coinage of the trade dollar was less than the exports, the shipments being \$691,406. The subsidiary silver coin was for the Department at Washington, and there are large orders ahead for the same account, which will employ all the time of the operatives during the remainder of the fiscal year. The business for the past ten months has been as follows:

	Gold.	Silver.	Total.
1875-76.			
July.....	\$1,780,000	\$ 728,000	\$2,508,000
August.....	3,840,000	670,000	4,510,000
September.....	2,740,000	674,000	3,414,000
October.....	2,440,000	678,000	3,118,000
November.....	1,820,000	803,000	2,623,000
December.....	1,920,000	800,000	2,720,000
January.....	1,940,000	617,000	2,557,000
February.....	2,352,500	780,000	3,132,500
March.....	2,280,000	1,028,000	3,308,000
April.....	2,780,000	609,000	3,389,000

Totals.....\$23,236,500 \$7,287,000 \$30,523,500

The gold coinage includes \$50,000 in eagles in February, \$45,000 in half eagles in September and March, and \$41,500 in quarter eagles in September and February. The silver coinage embraces \$4,082,000 in trade dollars for export, and the remainder in half dollars, quarter dollars, double dimes and dimes for the Atlantic States. The coinage for the current fiscal year is the largest in the history of the mint. For the same time in 1874-75 the total was \$26,622,000, or \$4,000,000 less than this year, of which \$23,320,000 was in gold and \$3,302,000 in silver. The descriptions for each year compare as follows for the period under review:

	1874-75.	1875-76.
Double Eagles.....	\$23,215,000	\$23,100,000
Eagles.....	50,000	50,000
Half Eagles.....	55,000	45,000
Quarter Eagles.....		41,500
Trade Dollars.....	2,619,000	4,082,000
Half Dollars.....	458,000	1,217,000
Quarter Dollars.....		128,000
Double Dimes.....		227,000
Dimes.....	197,000	1,351,000

Totals.....\$26,622,000 \$30,523,500

The coinage of trade dollars was intercepted none too soon. The country was being over-run with this stamped bullion, worth 10 per cent. discount in the open market, and yet forced on the community in large quantities at par. It was fast driving gold from all channels of circulation, which this unlimited manufacture of any kind of silver coins must eventually do. We hope therefore that we have seen the last of coinage for private account. There is enough work for the mints for a year to come in providing subsidiary silver coin for use in the Atlantic States, which ought to be limited to the amount of fractional currency withdrawn from circulation.

ORIGINAL COMSTOCK.—This is one of the oldest locations in the Gold Canon section, or in fact on the Comstock lode, being made by the famous Comstock himself, and the ninth location recorded in the Territory. It is to the westward of the Silver Hill mine, and very good developments were made in the early times, but not being properly worked or managed, it fell into obscurity and has laid idle till now, when it has got into the hands of men of capital and energy, who propose developing its real merits. Work is resumed upon it in the most practical manner. A tunnel has been started into the hill at a point which will cause it to intersect the ledge very shortly and follow it. This tunnel will develop the ledge to the depth of over 200 feet. A fine working shaft of three compartments is also started east of the ledge to open the mine at a much greater depth.—*Gold Hill News.*

NOTHING can prevent great loss to property in Salt Lake City by high water this spring. Every day increases the streams from the mountains, and the snow has just begun to melt. The banks of the canal along the western portion of the city have broken in a number of places and most of the farms and lots are covered with from a few inches to two feet of water. The lower part of the Fifth ward is a lake. Several houses are surrounded, the inhabitants being unable to leave their residences except in boats. There is no way to prevent the overflow, as the canals and waste ditches are not sufficient to carry off the flood.

THE C. & C. SHAFT.—Sinking the new shaft of the Consolidated Virginia and California mines is going steadily forward, the bottom still in porphyry, and the flow of water continuing at the rate of 40 inches. This water furnishes a great impediment to the rate of sinking, and must continue to do so until the flow is drained. This delay of the sinking must at the present rate of speed necessarily create a delay of nearly three months in the completion of the connection between the shaft and the 1500-foot level of the two mines. Otherwise everything is working as well as it is possible.

Butte County Mines.

Heretofore we have called the attention of our readers, says the Oroville Mercury, to the mines in the hills, at some distance from the town of Oroville. New companies have been formed, new mines opened, and new interests have been developed in those parts of the county, that we could not afford to let pass unnoticed. But now another enterprise has been started right here at home under our nose, and on ground almost classic, as it is well known to miners all over the State, who once had their home in this place but are now scattered. Just west of the depot, about a dozen rods, is a claim comprising some thirty-seven and a half acres, owned by E. P. Farnham, F. W. Day, George Miller, and Michael Lout. In an early day the ground was covered with cabins and the surface skimmed over. Later it was leased to Chinamen, who mined down some thirty feet, through three layers of pay dirt. This was as far as the company would allow them to sink. That the ground was rich and paid well as far down as the Chinamen were allowed to work, we need only state that for a small piece of the ground the Chinamen have paid the past winter the sum of \$2,100 in gold coin. This, only for the privilege of working down some thirty feet. Those who have lived here since the first mining begun, say that not less than \$2,000,000 have been taken out of this claim, and yet very little of it has been worked; only the top skimmed over. But the company is now going to mine it thoroughly. The bed-rock lays at a depth of 150 feet. Some years ago a shaft was sunk 120 feet and blue gravel and decomposed wood found with the richest of prospects, but the water drove the miners out. A competent engineer has been upon the ground, and informs the owners that he will put up a twelve-horse power engine and pump to match it, and will guarantee to keep the shaft dry to the bedrock. His offer has been accepted, and in a very short time the company will begin the work of sinking a shaft, four by eight feet, planked with heavy timber, and push the work both night and day, with three shifts of men working eight hours each, until the bottom is reached. They think bottom can be reached in forty or fifty days, after everything is in readiness. When once down drifts will be run and the dirt brought to the surface and sluiced off. There is no one who is at all acquainted with the ground but has the utmost confidence in it, and believes that each one of the company has a fortune in it. The only wonder is that some one has not undertaken it before, instead of going to distant places where a fortune has to be spent before any returns can be had. Here \$3,000 will cover all expenses up to the time of reaching the bedrock. We shall closely watch this enterprise and occasionally give our readers the result of what has been done.

Borax Lake.

The Coso Mining News says: Mr. D. Searles came in last Thursday from Borax lake, where are located his extensive works for the manufacture of borax. The lake is situated in Panamint valley, some 39 miles south from this place. The works are turning out 90 to 100 tons of refined borax per month. There are now on hand 4,000 sacks ready for shipment, the sacks averaging 85 pounds each. Mr. Searles says that George Hearst and others are working some very fine mines right across the valley from the borax works, in the Panamint range, and they have now on their dumps some 15 tons of high grade ore, going from \$1,000 to \$2,000 in silver. The ore is fine milling, being freely interspersed with horn silver. This is an old district known as the "Slate Range," and the mine now being worked is the old Antim, which in 1862 sold as high as \$100 per foot. The mine is relocated by Hearst, Reese and Hagin, of San Francisco, and is now called the Alta. A tunnel has been run in on the Alta some 300 feet, which brings them below the surface 75 feet; and at the face of the tunnel a winze has been sunk to a depth of 30 feet, good ore being found for the entire depth. The vein in the tunnel is 18 inches in width, but at the bottom of the winze it is two feet in width. On the Francis, Morrow and San Francisco ledges, a series of ledges one above the other in the hill, a tunnel has been run 600 feet, and it is thought the first ledge will be struck in about 20 feet further, which will bring them to a depth of 400 feet. The three ledges lie one above the other and 150 to 200 feet apart, so that when the tunnel shall have reached the second ledge it will be at a depth of about 550 feet, and the third about 700 feet. On the Lake View a tunnel has been run in about 100 feet, and some 25 feet further is yet to run to strike the ledge. Some six tons of ore have been taken out from the incline on the ledge, which was sent to San Francisco for reduction, yielding \$1,100 per ton. The four last mentioned claims are the property of Searles Bros., Skilling & Graesard. These were the old original locations made in the fall of 1861, the parties locating them having held possession and kept two or three men to work all the time developing them. Some three miles below the Searles Brothers' works are other works being run by Theophilus Dodge for an English company, Arthur Robottom being at its head. He employs five Chinamen and four white men. The Searles Brothers employ 26 Chinamen and 16 white men. Mr. Dodge started his works last November, and are now just getting in shape to crystallize. They have made no shipments as yet.

MECHANICAL PROGRESS.

Mechanical Specialties for the Centennial.

We find several notes in our Eastern exchanges of interesting mechanical works which are being accomplished especially for the display at Philadelphia. We describe a few of these as follows:

Bridges.

The Keystone bridge company will send to the exhibition the longest span weldless chord links for bridges ever made in this country; specimens of wrought iron tubular columns; a model on the scale of half an inch to the foot, of a Raritan trestle bridge, 472 feet span. The model is 21 feet long—nickel plated, showing all the details of construction of the trusses, central drum, and bearing wheels, and the engine, bailer, gearing and hydraulic machinery for operating and elevating the bridge. Also photographs of the St. Louis bridge, 520 feet span, and the machinery, cables, etc., used by the Keystone bridge company in erecting the arches, with a full size actual joint of arch and all its connections as used in the bridge. Also photographs of channel spans, Cincinnati, 420 feet and 520 feet spans. Photographs of Ohio river bridges at Piquetsburg, 350 feet span, Bellaire, 350 feet span, Fairmont, 348 feet span, and many other long span bridges erected by the company over the Mississippi river and in the Eastern States.

Shop Boys' Locomotive.

A locomotive is being built by the apprentice boys in the Philadelphia and Reading railroad shops, at Reading, the whole work being done under the direction of a young man who has not yet served his entire time with the company. It is a heavy ten wheel draft engine, cylinder 18x22 inches, and as it is to be built for exhibition at the Centennial, every part of the locomotive is receiving an extra finish. The casting and frame work are well scraped, the latter being finished on both sides. All brass work is to receive a high polish and finish. The main and parallel rods are to be bright, and the cab is to be of passenger finish and extra painted. Sprig hangers, equalizing beams, bolt heads and nuts are all to be milled off and finished with the greatest of care.

Steel Works.

The Baldwin *Taken of Progress*, says: On Monday, the 27th inst., the Pennsylvania steel company cast the largest steel ingot ever molded in this country, and equal to any made in England. The ingot is 10 feet long, and has 29 inches square section. Its solid contents is 100,000 cubic inches, and its weight 25,000 pounds. This mass will be sent to the Centennial exhibition, either in its present form, or will be forged into a shaft under the company's 14 ton hammer. The *Pittsburg Dispatch*, of April 15th, says: The Edgar Thomson works rolled this morning what, considering its weight, is claimed to be the longest steel rail in the world. It measures 120 feet, weighs 62 pounds per yard, and it is a perfect rail in every respect. Another rail, 96 feet long, was rolled. Both are for the Centennial.

Coal.

The Philadelphia *Bulletin* says: The Kitzing coal company have now on the Centennial grounds, ready to be placed in position, the largest specimen of bituminous coal ever taken from the mines. There are two blocks, both taken from the Franklin colliery, in Clearfield county. The smaller of these blocks weighs a little over two and one-fourth tons, and the larger will balance at about five tons. These immense masses of coal have been taken out the full height of the measure, and one can scarcely conceive the immense amount of labor and ingenuity required to place them on the cars ready for transmission. It was found impracticable to get the larger lump on the truck, and it became necessary to improvise a flat boat by which it could be dragged over the rails. The mass having been first strongly secured with iron bands and strong oak plank, was gradually worked upon the boat or flat, and six heavy mules attached. Their united force was, however, unable to move the immense weight, and at last a block and tackle was procured, by which the coal was gradually drawn out from the mine.

A LIGHTNING BOX MACHINE.—The following is a description of a box machine which turns out boxes directly from the paper pulp. The inventor is from Sherbrook, Canada. The pulp, when prepared, is received into a hollow cylinder, where it assumes the box form; it passes thence into a press, where its whole interior and exterior surface is subjected to a pressure of four tons to the square inch. From the press it comes out firm and hard as the best cardboard, but still damp; it is put into a drying rack and completely dried; then it is carried to a finishing machine, which, by further pressure, finishes it in any desired style, plain or embossed. The latter process is executed by the machine without outside attendance, and does not add to the expense of the box. From the moment the pulp leaves the "pulp engine" to the moment when the box is ready to be dried, the whole of the work is done automatically, without being touched by a workman's hand. In the whole operation of converting the pulp into the box ready for sale, only two boys or girls are employed—the one

to arrange the damp boxes in the drying rack, the other to feed them to the finishing machine. Collar boxes, four inches in diameter, and two and one-half inches in depth are turned out at the rate of 350 an hour.

AMERICAN MACHINERY FOR SIBERIA.—We are indebted to the St. Louis *Commercial Gazette* for the following interesting information: A St. Louis firm, Gerard B. Allen & Co., recently shipped 10 carloads of machinery via the St. Louis, Kansas City and Northern, Kansas City and Council Bluffs and Central Pacific railroads for San Francisco, from whence it will be transported to Nicholasvsk, on the Sea of Ochotsk, Siberia, by a steamship in waiting for it. This lot of machinery is for eight steamboats that are being built in Nicholasvsk by a Russian gentleman named P. J. Paholoff, who is engaged in steamboating on the Amoor river. His boats ply between the port at the mouth of the Nertschink, a point opposite the Chinese line, and situated at the head of navigation, or a distance of some 2,000 miles from the mouth of the river. These boats are used almost exclusively in the tea trade, and will carry cargoes of tea up to Nicholasvsk, on the Ochotsk sea, for shipment to San Francisco. The enterprise is a grand one, and the contrast of Mr. Allen is one which speaks well for the enterprise of the city. Much credit is also due Mr. A. C. Bird of the North Missouri; Geo. Olds, of the Kansas City and Council Bluffs, and J. C. Stubbs, of the Central Pacific, for the enterprise manifested in securing this shipment West, instead of by the Eastern route, via New York.

A NEW GUN.—The Indianapolis *Sentinel* says: A stock company is now being organized in this city, to provide for placing upon the markets of the world a military machine that is capable of firing over a thousand shots per minute, and can sweep the field from right to left, or vice versa, without having the position of the carriage shifted. There are six barrels (as with the Gatling gun), but they revolve and are discharged by the turning of a crank which propels the hammer. The cartridges are strung on a strap, 75 on each. When one is exhausted it can be replaced by simply slipping a hook. But one man is needed to operate the murderous weapon, and if perchance the enemy should storm the works, and the operator should see that he could not destroy or delay the advancing columns until reinforced, he could disable the gun by simply taking out the lock and putting it in his pocket as he fled the field. This would prevent his own gun being turned upon him—a decided improvement over the common cannons, which have to be spiked. The inventor is Mr. T. L. Bailey, late of Shelby county. He has letters patent from Washington on the gun, and a special patent on the lock, and has applied to the great powers of Europe for patents.

A NOVEL HOISTING CRANE.—There will be on exhibition in Machinery Hall a hoisting crane that is worthy of mention, which was constructed by Appleby Bros., of London, England. Its general appearance is something like a locomotive engine without the cab for the engineer and the fireman. It is a self-propeller, and used for the purpose of clearing away wrecks and lines of railway in case of collision or other accident. At the end farthest from the engine there is an arm of heavy timber, to which are suspended chains, hooks, blocks and tackle arranged something in the same style as the dredging machines seen upon the Delaware and Schuylkill rivers. The peculiarity of the machine is that it is self-acting; the arm revolves on a pivot near the front, it hoists and lowers about three tons weight, and is driven by a pair of six-horse cylinders, the stroke being about 10 or 12 inches. The wheels are joined by connecting rods and the usual propelling gearing. In order to insure steadiness in the lifting power, in front of the wheels there are patent "clutches," which are under the control of the engineer, intended to take hold of the truck and prevent slipping along the rails. This machine is worth about \$500.—*Am. Manufacturer.*

FRENCH STEAM WAGON.—The Paris *Figaro* says that a steam wagon was lately tried in hauling a train of artillery on a common road between the fortifications of Montrouge and Chatillon with entire success. Though the locomotive was light, with an engine of only 8-horse power, yet it drew a train weighing 20 tons up hill, down hill, turned round, and was entirely managed by one man, who fed the fire, started and stopped, and governed all the movements.

AN OLD ENGINEER.—There is an engineer running now daily, except Sunday, from Chambersburg to Martinsburg and return, on the Cumberland Valley railroad. He commenced in Moroh, 1839, as a fireman, and after the expiration of two years was appointed an engineer, which latter position he has occupied ever since, a period of 35 years, altogether fireman and engineer 37 years, giving entire satisfaction to the company. He is in the 66th year of his age, and his name is James Adams.

WEAKENING RAILS BY DRILLING AND PUNCHING.—The following experiment is mentioned by Hookney, in his "Manufacture of Steel." 1. A piece of rail with no holes in it stood a blow of one ton falling 20 feet. 2. A piece of the same rail with a punched hole through the web broke under the first blow at a three foot fall. 3. A piece with a drilled hole the same size, while it stood the first blow at a two foot fall, broke with the second blow at a four foot fall.

SCIENTIFIC PROGRESS.

A New Test Proposed for Arsenic.

Dr. Edmund W. Duvy has communicated to the *Chemical News* a new test for arsenic, or rather a modification of the application of the principle of Marsh's test. He writes: The metal aluminium, and more recently magnesium, have been proposed as substitutes for zinc in Marsh's process, or in Fleitmann's modification of it, as being less likely to be contaminated with arsenic than that metal. The modification which I would now suggest, and which, as far as I can ascertain, has not hitherto been proposed, is the employment of an amalgam of sodium and mercury as a means of generating the hydrogen required for the test; and by the use of this substance I do away with, altogether, the necessity of any acid, and I employ two metals which are not liable to arsenical contamination. As to sodium I am not aware that arsenic has ever been pointed out as one of its impurities, and as to its presence in mercury, that is, I believe, a circumstance of very rare occurrence; but, should it exist in that metal as an impurity, it can be readily removed from it by digesting the mercury in dilute nitric acid and afterwards well washing it with water. The amalgam which I have found to answer very well for the detection of arsenic consists of one part by weight of sodium to eight or ten parts of mercury, and is easily made by heating moderately in a test tube over a lamp the mercury, and then adding gradually in small pieces the sodium, taking care to keep away the face, if unprotected, from the mouth of the tube, lest some of that metal in an ignited state might be spirited out during the addition of the first portions. Those metals readily combine under these circumstances, forming an alloy that is liquid whilst hot but becomes hard and brittle when cold. The contents of the tube, while still hot and liquid, are quickly poured out on a clean plate, and, when cool, broken up in small lumps, which are then immediately placed in a well corked or stoppered bottle.

The way I employ this amalgam is simply to place the suspected solution or solid matter, along with a little water, in the bottom of a test glass; then add a small bit of the amalgam about the size of a grain of wheat, and lastly, place without delay, on the top of the glass, a piece of white filtering paper or the cover of a white porcelain crucible, moistened with a drop of a dilute solution of nitrate of silver, slightly acidulated with nitric acid, when, if arsenic is present, a dull black or deep brown stain on the paper, or a dark silvery one on the porcelain, will be quickly developed in the part moistened, owing to the silver of the salt being reduced to a metallic condition by the agency of the arseniureted hydrogen thus evolved.

Artificial Eyes Made Sensitive to Light.

Among the curious developments of science is the recent production, by Dr. C. W. Siemens, of an artificial eye that is sensitive to light. We wish we could add that it gives vision to the blind; but we cannot, though perhaps it contains a germ of promise in that direction. The new eye is composed of an ordinary glass lens, backed by an artificial retina of selenium. This mineral resembles and is allied to sulphur; it is distilled from bodies that contain sulphur in conjunction with metals, such as iron pyrites, a compound of sulphur and iron.

Mr. May, a telegraph clerk employed at the Valencia station of the Atlantic cable line, first observed, in 1873, that the electrical resistance of selenium was instantly altered by light, the resistance being diminished by increase of light.

Dr. Siemens makes use of this peculiarity of selenium in the construction of his novel eye. An electrical circuit is arranged, of which a bit of selenium forms a part, and constitutes the retina. When a strong light is admitted into the lens and falls upon the selenium retina, the current of electricity flows, and by acting upon small magnets may be made to work the artificial lids of the eye, opening or closing them according to the intensity of the light.

It is well known that the vibrations of musical sounds may, by an ordinary conducting wire, be electrically transmitted and successfully delivered to the ear. It remains to be determined whether light vibrations can, by means of selenium and electricity, be transmitted to the brain in the absence of the natural eye.—*Scientific American.*

NEW SUBSTITUTE FOR GOLD.—The following is a new metallic alloy which is now very extensively used in France as a substitute for gold: Pure copper, 100 parts; zinc, or preferably tin, 17 parts; magnesia, six parts; sal ammoniac, 3.6 parts; quicklime, 1.8 parts; tartar of commerce, nine parts and mixed as follows: The copper is first melted, then magnesia, sal ammoniac, lime, and tartar are added separately and by degrees, in form of powder. The whole is next stirred briskly for about half an hour so as to mix thoroughly, after which the zinc is added in small grains by throwing it on the surface and stirring it until it is entirely fused. On this being done the crucible is then covered and the fusion maintained for about 35 minutes, after which the surface is skimmed and the alloy is ready for casting. This alloy has a fine grain, is malleable, and takes a splendid polish. It does not corrode readily, and for many purposes is an excellent substitute for gold.

New Method for the Quantitative Analysis of Silver.

The method recently proposed by M. J. Volhard is based upon the circumstance that soluble sulphocyanide combinations with acid silver solutions form a white curd-like precipitate of sulphocyanide of silver. The same precipitate of sulphocyanide of silver is also obtained when silver solution is in the presence of the red solution of sulphocyanide of iron, the color of the latter disappearing instantaneously under the change. If, therefore, a solution of sulphocyanide of potassium or sulphocyanide of ammonium is added, drop by drop, to an acid silver solution, to which some sulphate of iron has also been added, every drop of the sulphocyanide salt solution creates a blood-red cloud, which, however, disappears upon the solution being shaken, the mixture assuming a pure milk-white color. It is only when all the silver has been precipitated as sulphocyanide of silver that the color of the iron and cyanide remains. If it is known how much sulphocyanide salt is necessary for the precipitation of a certain amount of silver, then it is easy to ascertain the exact quantity of silver contained in a solution.

This method is capable of being very generally employed, for it permits of bodies—such as chlorine, bromine and iodine—being quickly and surely determined by precipitating them with silver solution of known strength, the excess of the added silver being titrated back again by means of a solution of sulphocyanide salts. Especially for the determination of the above elements in organic combination is the new process of Volhard to be recommended. The method has many advantages over Mohr's process, in which bichromate of potash is the indicator.

1. It is carried out with an acid solution, while with Mohr's process a neutral fluid is necessary, thus curtailing at once its utility.

2. The combination—the color of which serves as an indicator—is soluble, so that the retroaction is more easily known.

3. The salt serving as indicator (the sulphate of iron solution) is itself uncolored, and can therefore be added in larger quantities.

To make his titrating fluid, Volhard employs sulphocyanide of ammonium. As this salt is too hygroscopic, in order to weigh it in particular quantities the solution is put into a silver solution, obtained by dissolving 10 grammes of pure silver in nitric acid, and diluting to 1,000 cubic centimeters. In another vessel a quantity of sulphocyanide of ammonium is dissolved in water, so that eight grammes are contained in every liter of water. Ten cubic centimeters of the silver solution are put into a beaker, and to it are added five cub. cent. of a pure solution of sulphate of iron (a liter containing 50 grammes) together with 150 to 200 cub. cent. of water. From a burette the sulphocyanide solution is gradually added, agitating the while, until the fluid has attained a feeble red tone. Assuming that for 10 cub. cent. of silver solution 9.6 cub. cent. of sulphocyanide solution have been used, 960 cub. cent. of the latter is diluted to 1,000 cub. cent. One cub. cent. then shows 10 or 10.8 milligrammes.

Before use, this solution is again tasted. With this object one gramme of pure silver is weighed, and this is dissolved in eight to 10 cub. cent. of nitric acid; this is heated upon a sand-bath until no further trace of nitrous acid fumes are given off, and to it are then added five cub. cent. of iron solution, the whole being diluted subsequently with 200 cub. cent. of water. On cooling, the sulphocyanide salt solution is added, while the liquid is kept agitated. With the last drop of the hundredth cubic centimeter the red color must have set in visibly and permanently.—*Dingler's Journal.*

ATMOSPHERIC CHANGES AND FIREDAMP.—The decrease of atmospheric pressure which this week has unloosed the spirit of the winds above ground, and probably occasioned a great amount of loss and damage on land and sea, has been no less a source of peril to the miners who work like the moles underground. The damage in coal mines, consequent especially on the sudden fall of the mercury in the barometer tube, is occasioned in this wise. When the glass is high and the pressure of the superincumbent atmosphere correspondingly great, the dangerous carbonated hydrogen is prevented from issuing from the walls and sides of the coal seam; when the pressure is suddenly lessened the gas escapes from numberless cracks and crevices, and accumulating, sometimes very rapidly, until it reaches the proportion sufficient with common air to produce an explosive compound, the naked light that is harmless under more favorable conditions suddenly takes effect and a deadly catastrophe is the result. In this way the barometer and barometrical warnings are almost as useful to the coal miner as they are to the mariner.—*Iron.*

BOUNDS OF MICROSCOPIC INVESTIGATION.—H. E. Sorby, President of the Microscopic society of London, says that with the most highly perfected instrument even the air is too coarse a medium to enable us to see the finest molecules of a substance. Prof. Helmholtz and other physicists claim that they are clearly able to distinguish lines separated from one another only 1-80,000 of an inch, and with the aid of photography and the blue light, can depict lines removed 1-112,000 inch, but we are able to see how far short even such an instrument comes, when we consider the millions upon millions of molecules that exist in ulmen and other substances, which only occupy a space of a thousandth of a cubic inch.

CHOICE VOLUMES.—We have a full new set of Scribner's Monthly—ten volumes—well bound, for sale at this office. Price, \$2 per volume.

29th, consider a proposition to increase its capital stock from \$5,400,000 in 54,000 shares, to \$10,800,000, in 108,000 shares.

It would appear from the above that the epidemic of increasing capital stocks of mining companies has come upon us again.

Senator Sharou's arrival from Washington seems to have had some effect on the stock market, or what was the same thing, people supposed it did, and Thursday was a livelier day in stocks on California street than has occurred for some time.

No Boiler Inspector.

The Judiciary Committee of the Board of Supervisors have reported that the appointment of a Boiler Inspector as provided for in the bill which passed the Legislature and was signed by the Governor, is not mandatory, but is left to the discretion of the Board. Boiler makers and engineers have all along been opposed to the new inspectorship as being useless and expensive, and there has been a very general and strong opposition to the new office. The report of the Judiciary Committee of the Board—Messrs. F. F. Strother, F. A. Gibbs and D. A. MacDonald—gives sufficient reasons why no appointment should have been made. It was as follows:

In the matter of the bill for the creation of the office of Boiler Inspector and the appointment of such officer, they report that after careful consideration and investigation they have come to the conclusion that the appointment of said Boiler Inspector as provided in said bill is not mandatory, but left discretionary with the board. They believe that the bill in itself, so far from proving a benefit to this community should its provisions be carried out, would prove an injury by offering opportunity for a system of blackmail and corruption. Within the past quarter of a century, during which time the community has had no such officer, there has been but one boiler explosion of note. Other cities where a similar law to the one under consideration is in force have frequent recurrence of these accidents. Boiler makers and engineers who have come before this Committee are unanimous in the opinion that the oftener boilers are tested the more liable they become to explode. They argue, and with good reason, that the oftener the plates are strained by the hydrostatic test the weaker they become. They show that the test proposed in the bill will exclude from the manufacture of stationary boilers certain kinds of iron which are now used, compelling makers to adopt iron of a much more expensive quality, though not superior for the purpose; that the Inspector cannot prove a boiler new in use made of English iron, and that a large stock of iron now in the hands of dealers cannot find any sale whatever, thereby working great hardship to a large class of our merchants. They conclude that as engineers, mechanics and iron men are more interested than any others in preventing boiler explosions, loss of life and damage to property, there can be no necessity for the appointment of a Boiler Inspector, who is only interested in his examination fee of \$3. Supervisor Gibbs, who has been assiduous in procuring evidence in this matter, brought before the Committee the heads of all the most prominent foundries, iron houses and boiler making establishments in the city, men who had been in the business from 15 to 25 years, all of whom were unanimous in the opinion that the law creating a Boiler Inspector is an absurdity, if nothing worse, and the office itself unnecessary and uncalled for. Wherefore your Committee have come to the conclusion that it is neither just nor expedient to proceed to an election for a Boiler Inspector of this city and county.

The report was adopted by the Board without a dissenting voice.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

MOLLIE STARK M. Co.—May 4th. Object: A general mining business. Capital stock, \$10,000.00. Directors—M. Higby, L. H. Van Schalk, A. Provo Kluit, A. T. Sweet and S. N. Putnam.

LAURENCE BURNETT M. Co.—May 4th. Location: El Dorado county. Capital stock, \$5,000.00. Directors—J. J. Laderich, J. E. Laderich, W. Kullberg, J. B. Crocker and N. Hueter.

NEW ERA G. & S. M. Co.—May 4th. Location: Alpine county, Cal. Capital stock, \$1,000.00. Directors—E. A. Hatherton, P. Ameraux, C. Wittram, W. A. Beal, E. F. Russell, G. W. Boyle and O. M. Grant.

SAN FRANCISCO AND CALIFORNIA G. M. Co.—May 4th. Location: Province of Ligua, Chile. Capital stock, \$1,000.00. Directors—W. B. Ewer, W. C. Quinby, W. H. Murray, A. H. Evans and A. B. Burns.

SOUTH PAXMASTER M. Co.—May 8th. Location: Nevada. Capital stock, \$10,000.00. Directors—M. A. Shepard, C. H. Stanyan, R. L. Taylor, L. Rice and Martin White.

JERRY LEROY DRICH & M. Co.—May 8th. Object: General mining business. Capital stock, \$300.00. Directors—J. B. Reynolds, A. J. Beverance, W. H. Reynolds, C. E. Buckingham and H. S. Smith.

CON. WYOMING M. Co.—May 8th. Location: Nevada. Capital stock, \$10,000.00. Directors—A. G. Burnett, V. J. Burnett, Charles Pace, J. J. Hicks and Charles E. Elliott.

SAN FRANCISCO AND NORTH PACIFIC R. R. Co.—May 10th. Capital stock, \$12,000.00. Directors—Leland Stanford, Mark Hopkins, C. P. Huntington, E. H. Miller, Jr. and C. H. Cummings.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver. 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.—**CLOREN DOWN.**—*Alpine Chronicle*, April 24: Manager Chalmers, having given the different grades of each checker ore a fair working at the mill, all to his satisfaction, will close down on the mill to-night, for the purpose of adding a 10 stamp battery and a furnace of 30 tons capacity. In the meantime ore will be raised from the mine, so there will be hundreds of tons ready for reduction when the mill and furnace are ready to run. When these improvements are completed our Loudon comb will not have to face so many Irish dividends.

ANOTHER MINE SOLD.—The Marion mine, at Monitor, has been sold to San Francisco parties, and a first-class company is being organized to push it to a development.

AMADOR.

MINING AT HUMBOLDT HILL.—*Amador Ledger*, May 6: The Italian company, who own a gravel claim on the other side of Humboldt hill, adjoining Truett & Bellard's mine, have constructed a bedrock flume and built a reservoir, and commenced mining operations on Tuesday. The claim prospects well, and is thought to be as good a gravel mine as there is in the county.

STUCK PAY DIRT.—The Austrian company, who have been engaged in running a tunnel into the hill near Jackson Gate, struck what is considered the main channel of pay dirt early in the week. The claim was bonded a short time ago, and will no doubt prove a paying property.

CLEAN UP.—*Stockton*, or "Lucky Dick" as he has been christened, has made another clean-up on his placer claim beyond Volcano. The amount realized is not definitely known, but from the fact that he is in the best of spirits and appears to be well supplied with coin, it is thought that he has gathered in another little pile.

GRAVEL CLAIM.—We learn that work upon this claim, located upon Sutter creek, is still being pushed with energy. No clean-up has been made, but the prospects which have been obtained show that the claim is destined to figure well in the placer mining in this county. The owners have already put themselves to much expense in getting the mine in working condition.

BUTTE.

HALF A MILLION.—*Groville Mercury*, May 6: The claim of O. P. Powers & Co. could not be bought for less than half a million dollars. In fact, it is doubtful whether the company would sell it at any price. Good judges declare it to be the best gravel mine on the coast, and as soon as the new ditch is brought in the work of mining will begin in earnest. With only 500 inches of water it pays anywhere along the river bluff at the rate of \$100 per day, and it takes only three men to do their work. It extends along the river bank for more than half a mile, and every inch of it will pay as much as that cleaned up last week. Strange that such a fortune should have lain so long upon the ground, and that the present owners should get it for the small sum of \$45,000. The claim was almost given away.

CALAVERAS.

MINES SOLD.—*Calaveras Chronicle*, May 6: The Mount Tmolus quartz mine, located in the Julius Maria district, formerly owned by Messrs. E. and M. Bigney, J. E. Tynan and J. A. Lefoy, has been sold to Messrs. Legare, of Chicago. The mine is one of the most promising in the county. We understand it to be the intention of the new proprietors to put effective machinery upon the mine immediately. We are not at liberty to state the sum for which the mine was sold.

WORKING COMMENCED.—The work of sinking the shaft in the Gwin mine has been commenced. Another 100 feet will make the shaft 1,200 feet in depth, at which point a level will be run. The batteries are now being supplied with ore from the slopes of the 1100-ft level, and sinking the shaft will not interfere with the mining and milling operations at all. The object is to keep a "gusher" going.

NEARLY COMPLETED.—The work of erecting one of Cooper & Cowles' giant mills on the Brady quartz mine, near Buckeye, is going rapidly forward and approaching completion. The hurdy-gurdy wheel that is to furnish the motive power is also being placed in position, and the 11-inch iron pipe necessary for conducting water to it is already on the ground. It is expected that the mill will be in readiness to commence crushing some time next week.

BRIEF MINING NOTES.—A contract has been let for sinking the shaft in the Grassehorn mine, at Mosquito, 50 feet deeper. Immensely rich rock is being extracted. Ore is now being hauled from the mine to Harris' mill. San Bruno, sinking. Good rock is being taken from the San Joaquin company's mine. A hundred tons of ore in the dumps.

COLUSA.

OUR COPPER MINES.—*Colusa Sun*, May 6: It is not generally known that Colusa county contains some of the very best copper mines in the State, and that work has been progressing on them very satisfactorily for some time. There is plenty of the very richest ore to be found, and the only drawback has been the cost of production. We now see that a new process has been put in operation at San Francisco, which reduces the most rebellious ore very cheaply. If this is so, the men who have held on to their claims will be glad to see good work done. The best of these are Julius Weyand, of Stony creek, and J. H. Lening, Jacob Williams and C. Kopf, of Colusa.

EL DORADO.

STUCK IT RICH.—*Mountain Democrat*, May 6: We caught a glimpse the other day of a few samples of the ore which J. H. Naper is taking out of his claim at Poverty point. It was chock full of threads and plates of gold, which would yield by hand-mortar process hundreds—perhaps thousands of dollars per ton. The ledge, where these specimens were taken out, is about three and a half feet thick, but of course is not all like these specimens have described. If it were, Oahu would pay off the national debt in six months.

NORTH SIDE MINING ITEMS.—"Toney" writes us from Greenwood, under date of April 29th, as follows: The Sliger mine is still being worked by a full complement of hands, and is, as usual, producing well. The first southern extension of the Cedarberg is about to be opened. The original Cedarberg is lying with interest, for some reason known only to the owners. I suspect a game of "freezing out." Mr. Deamarchie, an experienced miner, is successfully operating the French claim. At the St. Lawrence gravel mine a large amount of gold is being extracted, and report says that the mine is paying nicely. The Ausador mining company have commenced work on their location, with flattering prospects for a good mine. The Rozekrane mine is again free from water. I think that Superintendent Burroughs make a mistake in trying to work the mine with the machinery on the ground, the mine having been full of water most of the time this winter. But the mill is at present running every day and crushing very good ore. The rock is the richest ever seen in the mine, and it is rich in sulphur, which assay "pays up." The Mansfield mine, J. L. Smith, superintendent, is looking well. Mr. Smith informs me that the machinery is on the way for working the mine properly, including a Burleigh drill and engine complete. I was surprised to find this mine looking so well, as

common report was rather against it, but a large amount of labor has been done, and there is a fine lot of ore on the dump which looks well, showing gold in paying quantity. The superintendent informed me that the ledge is seven feet wide at the bottom of the shaft, the ore averaging same grade as that on the dump.

FRESNO.

FINE QUARTZ.—*Fresno Expositor*, May 3: Yesterday T. T. Strombeck left at this office a number of specimens of gold-bearing quartz taken from a vein lately discovered on Sprague gulch. The rock shows a large amount of free gold and is exceedingly rich. The ledge is about 30 inches wide and is well defined. It has been prospected to the depth of eight feet with encouraging results. Mr. Strombeck owns a liberal interest in the find, and he says he thinks it will beat Ten Jones' mine all to pieces.

INYO.

LOCAL NOTES.—*Conso Mining News*, May 6: In the De-fiance mine in the wide, north upper workings, at a depth of 40 feet, a drift has been started and run north a distance of 100 feet, developing a splendid body of ore for the entire distance, with plenty of it still in face of the drift. This drift will be continued so long as ore is found. Since last report a splendid body of solid galena ore has been struck in the drift running north from the south winze, at a depth of 125 feet. The new, or bolting shaft, has been sunk and timbered to a depth of 75 feet, the work being done in a splendid manner. When this shaft has attained a depth of 100 feet, drifting to connect with the south winze will be commenced.

INYO CONSOLIDATED MINING COMPANY.—Several weeks ago we mentioned the departure of Mr. Chas. Dale, who was formerly foreman for the New Consol mining company, on business in San Francisco, in connection with the formation of a company to operate in the development of some excellent mining property here. Mr. Dale made two trips to San Francisco in order to perfect arrangements. Last Sunday he returned and informs that his company, incorporated under the name of the Inyo Consolidated mining company, and owning the southern extension of the Lucky Jim, (one of the New Consol company's mines), have commenced active operations by the erection of blacksmith forges and grading for the new Inyo shaft. A contract is to be let immediately to sink 100 feet on the ledge.

ROSE SPRINGS.—L. Rodaspoitch came in from Rose Springs last Thursday evening, and reports everything there progressing very favorably, the mines looking well. Mr. Irwin, Superintendent of the Inyo mining company, is looking around for a better and larger supply of water for their mill, which they intend to build soon. He is now absent over to the Furnace creek country, some 15 or 20 miles from Rose Springs, to see if the fountain head is high enough to produce a sufficient pressure to send it across Death valley in pipes to Garabaldi mine.

A NEW DISTRICT.—A district called New Amargosa was organized about six weeks ago by Chas. Anthony, John Battle and Jas. Parker. It is situated southeast from Rose Springs 60 miles. Mr. Irwin says the gentlemen mentioned have located a number of mines which on top look very well. The veins are gold and silver bearing, the ore assaying very high.

CONSO CONSOLIDATED.—Work on the Bella Union has been prosecuted for a number of weeks past in explorations and preparing the mine for convenient working. About the middle of June extracting and smelting of ore will be commenced.

DEFIANCE FURNACE.—This furnace started up with its new improved water jacket (Shepard & Rawlings patent), on last Saturday evening at half-past eight o'clock. Our report, therefore, is not for a full week. There have been shipped, since last report, 452 bars of bullion; on hand, 218 bars. The furnace is running well indeed.

LASSEN.

MINING.—*Lassen Farmer*, May 6: A few parties have commenced prospecting and mining along the base of Diamond mountain. From reports we judge there is no trouble to get three dollar diggings along a considerable scope of country, with always the chance of finding something better. There is and will be an abundance of water for some time to come. There are a number of gold-bearing quartz ledges in the vicinity of these places, which, as yet, have never been prospected but little, and not to a depth sufficient to prove them. Work has been commenced upon one ledge recently. From what we can learn we do not believe there is a better section for the industrious prospector to strike valuable mines than that along the side and base of Diamond mountain. We shall endeavor to keep our readers posted on the result of the workings now going on.

LAKE.

LOCAL ITEMS.—*Lake County Bee*, May 4: From Mr. J. M. Davis, of Middletown, we gather the following local mining item: The Wall Street mine has a furnace working, and the mine is looking well. Within the last few days it has made developments of the finest character. The American mine has struck large bodies of high grade ore, and is reducing and shipping mail all the time. The London mining company has recently discovered a fine body of ore, and will probably erect a furnace the coming summer. The Napa Consolidated mine, of the Oak Hill country, has just finished a fine furnace, and have splendid prospects. The Porter and Cooke mine is having a bunch of retorts built. The Great Eastern mine, with Mr. Craven as superintendent, is looking well, and when their furnace is all under way, will be one of the best paying mines of the district. The Great Western mine is too well and favorably known to need any comments from us. Mr. Davis says they are shipping from 400 to 500 flasks of quicksilver per month.

NEVADA.

THE FRYER PROCESS.—*Football Tidings*, May 6: Crowds of people visited the Fryer works on Thursday, which was the grand opening day to the public. As they are now all ready to work ores on an extended scale, having perfected the last of the series of inventions comprising the process, we may expect very soon such a practical demonstration of its capacity to do what is claimed for it as shall completely set aside all doubts in the public mind.

FRANKLIN ALLISON RANCH.—The foundation work at this mine will soon be ready to receive the machinery. The hoisting works will be very complete when finished, the building to be 26 feet wide, 90 long and 22 high.

GOLDEN STAR.—Work on this mine is being pushed along lively. The new shaft has been sunk down to the ledge and the quartz looks fully as well as the last that was taken out.

HOMEWARD BOUND.—The contractors for putting up hoisting works on this mine are fast getting things in shape. They have the foundation timbers nearly all in place, ready to receive the machinery, and the masonry about the boiler is pretty well along.

OSAGE.—A large amount of work is now being done at this mine. They are retimbering and enlarging the shaft, which when completed will have a double track for ore and a pump and ladder way. They are also enlarging the mill, the blocks for two mortars being set and the building nearly completed over the new mill place.

PLACER.

GRATER.—*Placer Herald*, May 6: The main shaft in the Grater mine is now nearly 500 feet deep, and in the very bottom we find the rock is the richest ever seen in the mine. The report comes to be second-hand, though, to use the language of our informant, "the ore in the bottom is fabulously rich."

IOWA HILL.—Mining is now under full headway at Iowa Hill. Water is abundant, and nearly all the claims in the district are in operation. The clean-up

have been encouraging; business, in consequence, is good, and the citizens of that town look forward with reasonable anticipation of soon having one of the live-liest mining camps in the county, if not in the State.

MINING TREASURES.—*Dutch First Forum*, May 4: The break in the ditch of the South Yuba canal company, mentioned in our last issue, was repaired and water turned into it on Wednesday last; it only ran, however, a short time, when it broke again, and has been repaired and broken several times since. On Friday morning it broke in such a manner as to carry away the ditch of the Miners' ditch company. The South Yuba canal company has been exceedingly unfortunate lately, it appearing as though one break was hardly repaired before another occurred. We are informed that the Polar Star claim for the 17 days prior to Monday night were only enabled to wash 28 hours, which was done at odd spells. The last break was repaired and water was passing here on Tuesday. It is to be hoped that this time it will stay "put," as our miners having had such an unfavorable winter are now anxious to improve every hour. The break in the Miners' ditch mentioned above was repaired in 24 hours and water is passing through. The ditch of the Cedar creek company continues carrying its full capacity of water. The Yankee tunnel has been started up again; tunneling was resumed on Monday morning. It is the intention to drive it with all possible speed till the next shaft is reached. The Elmore Hill cleaned up on Tuesday. The claim is cleaning up. The Yankee, Hadger, Boston, Joho-haphat, Cental and the new claim are all washing to good advantage. The Polar Star claim started on Tuesday morning. At Gold run the Indian Hill and Cedar claims continue washing. The Gold run claim is washing at odd spells, much time being required to break boulders and blast up bedrock cuts. The Jackson or Miami claim resumed washing on Tuesday morning. This claim recently cleaned up with very satisfactory results; this, however, was the only clean-up this year, owing to the numerous breaks in the ditch of the S. Y. C. Co.; the owners were unable to obtain water. A blast of 60 kegs of powder was exploded in the Badger claim on Monday, doing splendid execution. A much larger blast, consisting of 300 kegs of powder, was exploded in the Elmore Hill claim on Tuesday, loosening an immense quantity of rock. Superintendent of the Cedar Creek company has introduced into the Yankee claim one of Hoskins' new mining lamps. The night foreman and all the men working nights in that claim assert that they do not want any more pitch wood, that the lamp gives a much better light than any fire jack they ever worked with.

PLUMAS.

PLUMAS.—*Plumas National*, April 29: The big mine is running very light at present, only about 50 men being employed. The water mill will be started just as soon as there is sufficient water from the ledge to run it. The Superintendent, Mr. Moore, is at present here. This company will be likely to lay in a much larger supply of wood hereafter, and not take chances of being out in consequence of a heavy winter. By the way, their beef contract will be let on the 1st of May, and those who propose to bid will have to be on hand. **HEAVY WORK.**—On Friday of last week the Maxwell company raised a railroad trestle 54 feet high, with braces, girds and all complete. From the time it left the ground till it was erected in its proper place was just 32 minutes. This is one of the 16 trestles for their high flume crossing Butterly creek. In the seven miles of ditch they are now building, the engineer reports about one and one-half miles of flume. Our old pioneer friend Maxwell is the Superintendent.

SANTA BARBARA.

THE QUICKSILVER MINES.—*Santa Barbara Press*, May 6: The Los Prietos and Santa Ynez mines are commencing work again, although on a small scale in comparison with last year. Every day miners are going out, and occasionally one or two come in and report things as getting lively. The prospect at present points to a successful year. Mr. F. Mahon, the superintendent, is thoroughly acquainted with quicksilver mining and will no doubt manage matters satisfactorily, but he will do well if he improve on the management of his predecessor, the late superintendent, Mr. Fred Homer, who is also an expert in mines, quicksilver in particular. Many a company lost a good mine when they got him gone. We were informed the other day that a miner who has arrived in town from that locality, that one or two important leads had been struck, and that work would proceed immediately.

Nevada.

WASHOE DISTRICT.

MEXICAN.—*Gold Hill News*, May 4: On the 1465-ft level, north drift is steadily advancing, and is following the east wall of the ore vein, the face showing some fine streaks of quartz. Further back, north of the Ophir line, a west cross-cut has been started to determine the character of the vein. The face of this drift is now in a very favorable formation. On the 1600-ft level of the Ophir, a drift has also been started north to penetrate the ledge immediately under the ore body resting on the 1465-ft level.

EAST OVERMAN.—This is a most excellent location, east of the old Overman claim, and in the main east range of the Comstock, and directly in the heart of the great ore belt. A splendid ledge of good lively quartz crops out at the surface, and under the present very able and efficient management a good and practical shaft of three compartments has been commenced, which is to-day down to a depth of 26 feet. It is all the way in quartz and the most promising ledge matter, and bids fair to develop good pay ore before many weeks. The company was recently incorporated.

CHOLLAR-FOTOSI.—Daily yield, 80 to 100 tons. Assay value, \$34 per ton. Sinking the main incline below the level the face still in quartz. Sinking the new combination shaft is making splendid progress. The erection of the powerful hoisting and pumping machinery at the new shaft is going steadily forward.

YELLOW JACKET.—On the 1940-ft level cross-cut Nos. 1 and 2 are being pushed steadily ahead. Cross-cut No. 3 has also been advanced eastward 20 feet, at which point a station is being cut out to sink a winze on the level below the 1940-ft level. The north and south drifts from cross-cut No. 3 are also being gradually extended north and south on the ore vein.

COSMOPOLITAN.—The apraise above the main tunnel level was up 124 feet this morning, and in very good average ore, some streaks of which show richly in free gold and assay very high. The main incline is steadily being driven ahead to the northward, following the vein, with the face in fair milling ore.

OPHIR.—Daily yield, 150 tons of ore. The new compartment of the shaft has been finished down to the head of the incline at the 1600-ft level. The entire works are now in the finest possible working condition. The south drift on the 1100-ft level is steadily advancing, the face still in quartz of a highly payable nature for the development of an ore body. The uprise from the 1300-ft level is now up nearly 100 feet, the face still in ore. On the 1600-ft level the south ore etope, which are now within about 150 feet of the California line, are yielding rich ore, the quality of which appears to be growing better as the slopes of the etope grow downward. The north drift on the 1600-ft level is also being advanced with Burleigh drills worked by compressed air, to reach and prospect the ore vein under where the ore was found a short time since in the Mexican mine. A west drift has been started on the 1600-ft level, 120 feet south of the Mexican, which is showing some very favorable prospects. On the 1700-ft level the damage done by the water is much less than was expected, and the north drift is now being cleaned out and repaired, preparatory to pushing it ahead into Mexican ground. The mill is kept steadily running on ore from the mine.

CALIFORNIA.—Daily yield, 350 tons of ore. The ore breasts continue to open up rich and handsomely as

the work of development progresses. The California mill has been kept steadily running on ore from the mine, and on the first of May the Sacramento mill was added to the crushing capacity. The yield of the California mill alone for the month of April will not fall short of \$1,500,000. The north drift, on the 1400-ft level, is steadily advancing toward the Ophir line, the face in a mixture of clay, quartz and porphyry. Sinking the winze below ground No. 3, on the 1500-ft level, is making the usual excellent progress.

CON. VIRGINIA.—Daily yield, 500 tons of ore. Everything has been running perfectly smooth with this mine until a day or two ago, when, by accident, the cylinder heads of the driving engines of the Brunswick mill were burst, so as to stop the entire mill. This is a serious drawback, as the cylinders cannot be replaced under 30 days, and the loss of the mill must considerably reduce the production of hullion for the month of May. It also cuts short that of April nearly \$200,000. The return of hullion from the mills for April will not now reach over \$2,250,000. The ore slopes are looking splendidly, and there are no changes of interest to report of any portion of the mine. The grading for the great ore of new deep battery mill below the C. & O. shaft has been commenced. The machinery for both the battery and amalgamating mill is now being forwarded and will soon all be on the ground ready for erection.

LADY WASHINGTON.—The pump-ho arrangements at the 600-ft station are about completed. The shaft has penetrated over 40 feet into the most promising ledge matter, with strata of quartz and low grade ore, but lately exposure to the air has shown it to be of that peculiar swelling nature so frequently encountered along the Comstock range, crushing in the heaviest timbers with a gradual but irresistible force. This has necessitated a suspension of sinking the last two or three days in order to ease up and secure the timbering. There is no increase of water, the pumping and other machinery works splendidly, and sinking will be proceeded with at once under the most favorable auspices.

COLUMBIA.—The mine has a very favorable location, adjoining the Senator on the north and lying just east of the Gould & Curry. A fine shaft, with two compartments, has been sunk to a depth of 365 feet. Recently Mr. J. C. Lennon received the appointment of superintendent, and seeing the immediate necessity of having another compartment commenced at once to enlarge the shaft by raising up a third compartment from the bottom. This work is now well under way.

JUSTICE.—The ore in the slopes on the 600-ft level is showing better as the slopes are more developed. The upraise from that level to connect with the 400-ft level is also in good ore. The winze below the 800 has reached the 1000-ft level, and a cross drift has been started to connect with another cross drift now being run from the main shaft drift on the 1000-ft level for that purpose.

BULLION.—The northeast drift on the 2000-ft level is steadily advancing toward the ledge, the face still in the hard black dikes heretofore spoken of. The face seems to be softening somewhat and the seepage of water steadily on the increase.

KOSCIUSKO.—During the last part of the week a heavy flow of water burst into the south drift on the 500-ft level, driving the men out and flooding that portion of the mine. The pumps not only held their own, but at the end of three days began to gain on the flow, when by an accident the pumps were disabled and the water rose rapidly in the shaft. By yesterday noon, however, another pump had been set to work and the water is now being rapidly lowered, and will probably all be out in a very short time. This water comes from the ledge, and when taken out will drain the mine down to the 500-ft level.

DAYTON.—The water has been drained from the shaft and the sinking below the 700-ft level was resumed this morning. The 700-ft station has been completed and the drift running to cut the ledge at that point is advancing rapidly. The north and south drifts on the 500-ft level are each pushed steadily forward, still following the east wall of the ledge, with many indications of soon opening a fine mineral vein. Nearly 900 feet of the ledge on this level has now been laid bare, ready for cross-cutting.

SIERRA NEVADA.—Sinking the main shaft is going steadily ahead, the bottom in good working ground. The north drift on the 1500-ft level is steadily advancing, the face still in quartz and ledge matter.

JULIA.—Sinking the shaft is making the usual good rate of progress. The station at the 1300-ft level has been opened and a drift started to prospect the ore vein at that point. Should the concentration of the quartz and ore continue to improve in the same proportion as on the level above, there is hardly a doubt but a paying vein will be opened.

PROSPECT.—Shaft 218 feet deep to-day. It was turned over into the hands of the present contractor on the first of the present month and is sinking deeper goes forward very energetically. The Ingersoll rock drill is employed to very good advantage in doing this, making with their assistance about four feet per day.

KNOWSRECKONER.—The work of sinking the main shaft is progressing well, about two feet per day. The rock in the bottom of the shaft is quite hard but works well. The water in the mine has decreased a little.

WARD.—The shaft is down 65 feet. The south drift on the 1000-ft level of the Julia shaft is steadily advancing toward the Ward line, the face in a very favorable description of ground.

BRUCE.—The shaft is down 400 or 400 to 10. There are no material changes in the mine at any point. Sinking the air shaft for the reception of the pumps is making the usual good progress. The erection of the new pumping machinery is going forward at a very rapid rate.

MINT.—The shaft is now down 70 feet below the 1000-ft level, the bottom being in soft ledge material. The flow of water remains unchanged.

SILVER HILL.—Sinking the main ledge is again progressing at a fair rate of speed, the bottom in hard blasting ground. It is now down 169 feet below the 440-ft level.

AMAZON CONSOLIDATED.—Sinking the main shaft is making good progress. The north drift, which has penetrated into the Glasgow ground, is showing some fine sulphuret ore in streaks.

SUCCON.—Sinking the main shaft is still going ahead at a very lively rate. The flow of water is still strong at the bottom, but is easily handled by the pump.

TROJAN.—The new hoisting works and machinery are rapidly approaching completion.

OVERMAN.—Sinking the shaft has made the usual progress during the week. The rock is still very hard and the flow of water strong.

IMPERIAL.—The north drift on the 2000-ft level is still in ore of a good character.

GOULD & CURRY.—Everything is being done that is possible to forward the completion of the foundations for the new pumping machinery. The repairs to the shaft are making favorable progress.

SLABBER.—The new machinery for the pumping shaft is being placed in position as rapidly as the workmen can perform the necessary work.

LADY BYRON.—All possible energy is being used in making the excavations and putting in the foundations for the reception of the new hoisting and pumping machinery.

GROSE CONSOLIDATED.—Everything in and about the mine is again in fine running order, and the north and south prospecting drifts on the 300-ft level are being steadily advanced.

NORTH CARBON.—The erection of the new hoisting works goes ahead energetically. The hoiler is in place and the other machinery will soon be. The main building is 75 feet long by 30 feet wide, the boarding, house and other requisite buildings are in good shape, and the new works will be steamed up in a very short time, when active mining operations will be inaugurated.

NORTH CONSOLIDATED VIRGINIA.—The shaft is down

275 feet. It is the intention to open a station and put in water tanks for catching up the flow at the 900-ft level whenever that point is reached. The appearances are that the ledge is not far away.

CROWN POINT.—The south prospecting drift on the 1700-ft level is steadily advancing to connect with a winze being sunk from the level above for air purposes.

NEW YORK CONSOLIDATED.—Preparations are now being rapidly completed for driving the prospecting work of this mine in a more vigorous manner than it has ever been done heretofore.

BALTIMORE AND AMERICAN FLAT.—The 1250 ft station is opened and a water tank is being put in and the pumps lowered to that point. A drift will now be started to cut and prospect the ore vein at that point.

UTAH.—Sinking the main shaft proceeds steadily, the bottom still in hard porphyry. The rock blasts well, but admits of only a slow rate of speed in sinking.

UNION CONSOLIDATED.—The north drift on the 1300-ft level is steadily advancing, the face in quartz and soft ledge material. The drift from the bottom of the winze on the 1465-ft level is entering a very favorable ledge formation.

REX AND WARD CROSS.—The shaft is well and thoroughly timbered from top to bottom, but its depth now necessitates the erection of hoisting machinery.

FLORIDA.—The shaft is in good repair and the water reduced to below the 400-ft station. The drift to the ledge at that point is now being cleaned out.

DANEY.—The water has been extracted to below the 400 ft station, and a new water tank is being put in at that point.

NEVADA.—The main drift north is still pushing ahead, and since last report has run into porphyry and clay. The superintendent thinks this is the outer wall of the main ore chimney found in the level above.

WOODVILLE.—Nothing is yet being done in the mine, owing to the unsettled state of some of the old accounts. It is expected that everything will now soon be settled up ready to resume sinking.

BROOKS.—Sinking the shaft going steadily ahead in the most energetic manner. The prospect of the mine are of the most favorable character.

NIAGARA.—Sinking the incline shaft is pressed ahead with all possible energy. As soon as a sufficient depth is attained a station will be opened and drifts started to prospect the ore vein.

LAROE.—Preparations are being made to erect good substantial hoisting works.

HALE & NORCROSS.—The shaft is again in splendid condition for good work. The erection of the new pumping machinery is progressing at a rapid rate.

CALEDONIA.—The rock still continues hard at the bottom of the shaft. The flow of water is still strong.

LEVATHAN.—The station at the 600-ft level is opened, well timbered, and the main drift for the new tunnel well under way.

SENIOR.—Are yet at work hoisting water, but a few shifts more will drain it all out, when sinking the shaft will be resumed.

PHIL SHERIDAN.—The machinery is all in first class working order, and work in the mine has been resumed in good earnest.

WEST BELMONT.—Drifting both west and northwest is going ahead finely, with the face of each drift in low grade ore.

(Continued on Page 316.)

Naming the Mines.

How and Why They Received Their Appellations.

The discoverers of bonanzas are getting up prettier names now-a-days for mining claims than they used to when such titles as Puite, Belcher, Mary Ann and Brown were considered good enough. The names given to claims sometimes indicate the individual tastes of the owners and sometimes their nationality. The Mexican was named by a Greaser, and the City of London by a "bloody Britisher." Any one would know that a native of sunny Spain was the original locator of the Dios Senor or the Del Rey. Some military gentlemen thought West Point could be made to pay dividends, and a 49er thought he had "struck it" when he found the Argonaut. The man who bet that Missouri's metropolis was the biggest city in the world now thinks the St. Louis is the richest mine on the Comstock lode. Tam O'Shanter was probably named by an admirer of Bobby Burns, Hector by a reader of the classics, Snustor by an aspiring politician, and Sally Hart by some devoted slave of uncompromising cheek and red hair. The Sullivan was staked off by a son of the Emerald Isle, Germania by a patriotic Teuton, Buckeye by a native of Ohio, Hartford by a nutmegger, Delay by a lazy man, Blue Jacket by an old salt, Lafayette by a Frenchman, Beethoven by a lover of sweet sounds, Plutus by a Hard-shell Baptist, Dexter by a left-handed man, and Burning Moscow by a subject of the Czar. A Third Termer calls his location Grant, and one who helped to "clean out the valley" thinks Phil Sheridan a good enough name. An old miner thinks he has a Prospect of getting rich at last. Rocky Bar and Nigger Ravine smack of old days in California, while Silver Leaf and Brilliant belong to the new order of names. But what matters it after all, whether they are called Ceresus or Poorman, Consolidated or Segregated, so long as they pay dividends or levy assessments? They are bought on margins and sold short just the same, and sooner or later fall into other hands, leaving the first owners poorer than when they began. There seems to be a fatality in the matter, for while a few have been able to hold on to their mines and get away with the profits, the great majority of prospectors and miners lose not only the property itself, but all the money expended by them in its development. —*Gold Hill News.*

THE NEW SILVER DOLLAR.—Morrill, of Virginia, proposes the following amendments to the bill pending before the Senate: To make the weight of the new silver dollar 450, instead of 412 8-10 grains, troy; to make its legal tender limit \$5 in any one payment, instead of \$20; to make the new silver dollar exchangeable by the Secretary of the Treasury for United States notes of denominations of less than \$5, commencing with the lowest, instead of allowing all United States notes to be thus retired; to insert a new section providing that after 50,000 of the new silver dollars shall have been issued they shall thenceforth only be issued in exchange for gold coin, at par; finally, in place of Bogy's amendment to fix the legal relative value of gold and silver at 15 1/2 to 1, Mr. Morrill proposes to make it 17 1/2 to 1.

THE ENGINEER.

Channel Schemes.

How to escape the boisterous channel and go from England to the Continent with level head and quiet stomach is still the problem which engages the European engineers and capitalists. There are now chiefly considered two projects—the tube railway and the tunnel. We propose to give the latest points of these two schemes.

The Tube Railway.

At a recent meeting of the Society of Engineers, London, a paper was read by Mr. Perry F. Nussey, C.E., on the channel railway proposed by Mr. P. J. Bishop, but the details of which were worked out by the author himself. The system consists of two distinct tubes of cast iron, each carrying a line of rails laid on the bed of the channel between Dover and Cap Grisnez, a distance of 21 1/4 miles, at an estimated cost of £1,000,000 per mile. The tube, which is elliptical in section, would be four inches thick, cast in five feet lengths, bolted together by internal flanges, lined inside with brickwork laid in cement, and that cased again with five-eighths inch boiler plate; the outer dimensions 17 feet 8 inches diameter of the major axis, and 14 feet 8 inches the minor axis, the inner diameters being 15 feet and 12 feet respectively. The tube would be sunk in 25 feet lengths, an ingenious water-tight bulkhead being fixed at each end, with a central guide to bring them in juxtaposition for bolting when they are sunk. The bulkheads are removable from the inside, and would be sent on shore in a trolley as the tube progressed, to be used for a fresh section. The operation of sinking would be carried on from a floating pontoon 400 feet long by 100 feet wide, with a central opening 100 feet by 25 feet, surrounded by staging for lowering each section. Plans were shown of the details of this novel scheme, for which the author claimed that it was perfectly practicable, and that it could be completed for this estimate in five years, or, if necessary, in three years.

The Tunnel.

In the latest issue of *Van Nostrand's Magazine* we find some interesting particulars of the engineering nature of this proposed channel tunnel. The distance across the channel at the point selected is about 22 miles, but as considerable approaches will be necessary on either shore, in order to reach the level of the tunnel entrance, the entire scheme will embrace about 31 miles of railway. In the first instance shafts will be sunk on each shore to the depth of 450 feet below high water mark, and, from the bottom of these, driftways will be driven for the drainage of the works whilst in progress, and for its permanent drainage after completion. The tunnel, which will be very similar to an ordinary railway tunnel having two lines of rails, will commence 200 feet above this driftway, and will be driven at an inclination of one foot in 80 to the junction with the drainages driftway, and then at a gradient of one to 2,940 to the center of the straits, where the tunnel from the English shore will meet that driven exactly in the same manner from the French shore, and, being united with it, will complete the submarine railway under the channel. The drainage will be from the center of the tunnel to either end.

In the execution of this work a driftway, nine feet in diameter, will first be carried right through, and this will afterwards be enlarged to the full size of the tunnel. The problem of the execution of the tunnel in a reasonable time has been simplified by the invention of tunneling machinery, and the machine of Mr. Dickenson Baunton, which has been tried on a practical scale by the company in the lower or gray chalk, has been quite successful. The machine works like an auger boring a hole in wood. The chalk is cut off in slices, which break up and fall upon an endless band, which loads them into wagons behind the machine. The apparatus was tried by the company at Messrs. Lee's cement works, Snodland, near Rochester, in the gray or lower bed of chalk, such as underlies the channel. It made a driftway seven feet in diameter, and it advanced at the rate of from a yard to a yard and a quarter per hour. At this rate it would only require two years to drive a driftway of seven or nine feet diameter from one side of the channel to the other, a machine being started from each side. The cost of driving a heading would consist—1st, of tunneling machines, pumps and pumping engines; 2d, the hand labor, which would not be considerable, as the machine requires but few hands to work it; and, 3d, interest on the capital expended during the execution of this work, which might last two years or more. Taking these three elements of expenditure into consideration and according to the calculation of experienced contractors, it has been found that the driftway could be executed for £800,000, if it required only two years to make it.

As soon as the driftway was completed the success of the undertaking would be assured. It would furnish the necessary data for an exact estimation of the cost of the whole work and the time necessary for its execution. In fact, all that would be necessary would be to enlarge the driftway to the dimensions of an ordinary railway tunnel. It has been estimated by some engineers and contractors of considerable ex-

perience that after the driftway was finished, four years' time and four millions of money would complete the work, including the junctions with the English and French railways on either shore. Sir John Hawkshaw and the engineers associated with him, however, think it prudent to double this estimate both of time and of cost, at least until the preliminary work shall have given them the necessary data for a more exact estimate of the duration and cost of the work.

Preliminary steps to test the practicability of the project are about to be put in hand without further delay, for which purpose an English and a French company have been promoted to carry out experimental works on either side of the channel. An act has been passed by the British Parliament during the past session to enable the English company to acquire the necessary lands at St. Margaret's Bay, and it is understood that a *projet de loi* has also been passed in the French Senate to confer the necessary powers on the French company. The works to be undertaken by these two companies consist of sinking two shafts—one on either coast—about 150 yards deep, from which an ordinary mining drifting about half a mile long will be driven under the sea. This work would be a true beginning of the proposed permanent tunnel. Its cost is estimated at £160,000, of which sum it is understood the two companies will find £20,000 each; the Rothschilds of London and Paris have each undertaken to find similar amounts; the Chsmn de Fer du Nord will contribute £40,000, and the London, Chatham, and Dover and South Eastern railways will respectively subscribe £20,000. It may now be confidently anticipated that the commencement of this great work will not be delayed.

A New Bridge Proposed Across the St. Lawrence.

The latest project which comes to us from the important work of bridge building is the proposed "Royal Albert bridge" across the St. Lawrence river. The April number of the *Canadian Mechanics' Magazine* contains full drawings, specifications and bird's-eye view of the structure. The engineer whose design is illustrated is Mr. Charles Legges.

The total length of this bridge and viaduct will be 15,500 feet, or within a fraction of three miles; and the extreme distance covered from the point of departure from the Quebec, Montreal, Ottawa and Occidental railway on the Mile End heights, to the junction with the line on the south side, will be five-and-a-half miles. A sufficient length on the natural surface of the ground on St. Helen's island exists between the two bridges for siding purposes. Trains from opposite directions can thereby cross each other here, and so double the capacity of this bridge. The piers to be placed in the two channels of the river will be designed on the general principles of those of the Victoria bridge, for the purpose of allowing the ice to cut freely past. Those in the navigable channel will be sunk in caissons, thereby obviating the use of cofferdams and other obstructions in the river, and rendering pumping unnecessary. In the south channel the water is very shallow, with a rock bottom, and very little expense will be incurred in putting in the foundations of the piers. The abutments and piers on the land portion will be of simple design, the first probably partaking of the Egyptian style.

The iron superstructure from end to end will be composed of four independent longitudinal ribs, or open lattice girders, placed certain distances apart, and strongly connected laterally. These ribs will be provided with the usual friction rollers on each alternate pier, to provide for expansion and contraction. Between the two inner girders, on the lower floor, will be a space of 18 feet to accommodate two tracks or trains of city cars, to be drawn by dummy engines. Between the two inner girders and outside girders, on either side of the bridge, will be spaces of 14 feet respectively, for ordinary cart and wagon traffic, passing in one direction on the western, and in the opposite direction on the eastern side of the bridge. Exterior to these two outside girders will be footwalks, firmly supported on brackets of iron, strongly attached to the side girders and floor beams; they will each possess a width of eight feet and be provided with ornamental railing for the protection of pedestrians.

At a distance of 15 feet above the lower floor will be placed a second one, strongly connected and braced with iron kelsons and gussets to the longitudinal girders; on the floor, between the two inner girders, will be placed a railway track with crossing arrangements for trains, as before stated, at St. Helen's Island. The apices existing between the inner and outer girders will each possess the width corresponding to the carriage-ways below, and are intended for carriages and other vehicles requiring a higher rate of speed than carts or wagons. Should a second track ever be required for railway purposes, across the entire length of the river, a fifth girder can be erected on the upstream side of the bridge, and be supported by iron columns from the saddles of the ice-breakers, at a comparatively small cost.

The entire height of the bridge from the surface of the water will be 210 feet for the centre span, or 250 feet from foundation.

A LITTLE strong soap lather mixed with the starch will prevent flat irons sticking to linen.

USEFUL INFORMATION.

Gilding on Exposed Ironwork.

Some of our foreign exchanges have been discussing the use of gilding upon exposed iron work. One of them takes the ground that the only result of gilding can be the destruction of the iron, gold standing at the head of the electro-negative bodies, and powerfully tending to promote the destruction of iron when the two are in contact in the presence of air and moisture. The gold size by which the gold is held in place, the paint beneath and the gold itself are supposed to be so mere network permitting the air and moisture to find their way to the surface of the iron beneath, and thus to establish a chemical action which destroys the iron. Theoretically this is very true, but the case has not been fairly stated. The paint when first put on is not porous, and, until the action of the air decomposes them, they prevent air and moisture from coming in contact with the iron. As they decay they become porous and air and moisture find ready entrance. Gold, so commonly applied to iron, is put on over a coating of gold size applied on top of the paint. The iron in this manner gets a much better protection than it could otherwise have. The gold is next applied, and serves to protect the paint beneath, and, if well put on and of fair thickness, will preserve the paint and size much longer than they would last if exposed to the weather. Now, as long as the gold preserves the paint, the gases or moisture in the air will have no opportunity to attack the iron, and so the galvanic action so much dreaded will have no opportunity to begin. Gold leaf, as commonly used for such purposes, is very thin and usually falls off holes; in time the air acts upon the paint through these, and so reaches the iron, when, of course, the action is rapid. But it is to be noted that the action of the air is greatly retarded, and a gilt surface of iron in this climate lasts much longer than one simply painted. We apprehend that more trouble has arisen from a poor quality of gold, easily destroyed by the weather, than from gilding done with real gold leaf of good thickness, well laid. The poor leaf yields to the action of the weather, the paint beneath is then attacked and the destruction of the iron rapidly follows, whether there is any galvanic action or not. We look upon gilding as a very desirable method of ornamentation, especially when well done, and think it just as safe as painting in any event.—*Iron Age.*

How to Make a Good Scarecrow.

Crows are possessed of much more wisdom than is generally credited to them; and while an immovable bundle of rags may drive them away for a short time, we believe that eventually they discover the humbug, as we have seen the birds complacently picking up young corn almost within the shadow of an elaborate stuffed scarecrow as ever erected. We, however, have heard suggested a couple of plans which are calculated to intimidate even the boldest of these birds; and as they are easily carried out, perhaps our farmer readers may make use of them. The first and best is a suspended looking glass. Take two small cheap mirrors, fasten them back to back, attach a cord to one angle, hang them from an elastic pole. When the glass swings in the wind the sun's rays are reflected all over the field, even if it is a large one; and even the oldest and bravest of crows will depart precipitately should one of its lightning flashes fall on him. The second plan, although a terror to crows, is especially well suited to fields subjected to the inroads of small birds and even chickens. It involves an artificial hawk made from a big potato and long goose and turkey feathers. The maker can exercise his imitative skill in sticking the feathers into the potato so that they resemble the spread wings and tail of the hawk. It is astonishing what a ferocious-looking bird of prey can be constructed from the shoddy simple materials. It only remains to hang the object from a tall bent pole, and the wind will do the rest. The bird makes swoops and dashes in the most headlong and threatening manner. Even the most inquisitive of venerable hens has been known to hurry rapidly from its dangerous vicinity, while to small birds it carries unmixed dismay.—*Scientific American.*

Novel Cork Leather.

G. E. Block, of London, Eng., writes: I take sheets of cork, and apply, with a brush, to one side of them a coating of india rubber solution. When dried, I apply a second coating. I then take a piece of japanned cloth, canvas, thin leather, or other such like fabric, and similarly coat it at the back with two coatings of the solution, and then place the coated surfaces of the cork and fabric together, the edges of the pieces of cork being fitted together neatly, so as to form a continuous sheet or layer. The uncoated side of the cork, and also another piece of linen, cotton, or other fabric, are now similarly coated with two coats of the solution. When the coatings upon the cork and linen are quite dry, the coated surfaces are applied together, and the cork, now coated on both of its sides, is submitted to considerable pressure in a press or stamp, or by rollers.

In order to cause the coated surfaces of cork and fabric to adhere firmly to one another, it is better that the pressure should be applied sud-

denly, as by a blow, or by stamping or rolling. The two coatings of cementing solution which are thus brought together blend and form a perfect skin, which will bend at will, and which can be turned in any way, and yet always return to its original form without breaking.

As each of the coatings of cementing solution has been allowed to dry before bringing them together and submitting them to pressure as above described, the solution will not penetrate the outer surfaces of the fabric or material and spoil their appearance.

Uses of Mustard Seed Oil.

R. Rother, in the *Pharmacist* for April, calls attention to mustard seed oil as being well adapted to the preparation of all the official ointments, cerates and plasters, to the exclusion of lard or other glycerides which are changeable and unsatisfactory.

A mixture of three parts of mustard oil, one part of spermaceti, and one part of yellow wax, is in every way superior to the official simple ointment. The spermaceti in this mixture is not essential, as three and one-half parts of oil and one and one-half of wax answer equally well. When substituted for olive oil in cerate of sub-acetate of lead, the yellow color disappears after a few days, and the cerate becomes white. The main advantage, however, lies in the fact that the preparation does not become rancid.

Resin cerate, of a superior quality, results from a mixture of 14 parts mustard oil, 12 parts resin and four parts yellow wax.

Ointments containing ingredients liable to change under the influence of lard or olive oil, as, for instance, ointment of iodide of potassium, or rose water, are properly prepared with mustard oil. The ointments of sulphur, carbamate of lead, and oxide of zinc, retain a smooth grain and the appearance of freshness perfectly, when prepared with mustard oil.

GOOD HEALTH.

The Sanitary Side of Soap.

In the *Sanitarian*, L. D. Bulkley, M. D., writes: The subject of soaps for the toilet is one of very great importance, and one which our sanitary authorities would do well to take in hand, when we consider their enormous consumption on the one hand and the practical facts in regard to their manufacture on the other. It is no idle matter what one rubs on and into the skin, and it is a very frequent occurrence to have ointments which, when fresh, are not only harmless and unirritating, but even soothing, become most pernicious by having turned rancid. What shall we say, then, in regard to the fearful decomposing masses of animal fats which go to make up the soap manufacturer's stock, and which are returned to us colored and perfumed as the finest toilet preparations? It is true that the fats, in order to become saponified, undergo a disintegration with the alkali, but this is quite a different affair from the decomposition which takes place in the family refuse jar, whose contents find their way through the soap-fat man, and those to whom he sells, back again into our bedrooms to cleanse our persons with.

We know scientifically that certain specimens of soap, when submitted to microscopic examination, have been found to contain pus cells, and other minute spiculae of bone, other fragments of animal connective tissue, etc. These examinations have been instituted on occasions when eruptions on the skin have been found to persist and recur with the use of a particular kind of soap; and I doubt not but that, if time could be spent at it, the same foreign elements could be found microscopically in very many of the samples of our soaps now in most common use. There is no doubt but that many cases of diseases of the skin are thus originated, and many more kept up indefinitely by this cause, and I could readily cite examples in support of this assertion.

I have written thus at length because I believe there is a remedy, and that is in the use of soaps made either from the vegetable fats and oils or from those of fish—that is, if they are used in a fresh state. As an example of the former we have castile, almond and palm soaps—of the latter the potatoe oil soap of the Germans (*sapo viridis*), which Hebra has made famous for the treatment of skin diseases; the former being made, as is known, of olive, almond and palm oils respectively, combined with soda; the latter of spermaceti, or cod liver oil and potassa, although all these articles are undoubtedly subject to adulteration, the refuse animal oils and fats being much cheaper than the proper constituents.

How Vegetation Affects Health.

The *English Gardeners' Magazine* says: Our instinct leads us to delight in flowers. Their beauty and perfume have irresistible attractions for us. We have little dreamed that we were thus led to surround ourselves with objects which most powerfully conduce to health. No doubt there are certain members of the vegetable kingdom which are exceedingly deleterious; for, not to speak of the much dreaded upas, the West India manchineel and some of the American rhus, there are some of our common sweet scented flowers, such as the mezerion, which have very injurious properties. But recent investigation has proved that those

adornments of our gardens, for the presence of which we so crave, are as a rule endowed with health preserving qualities. Oxygen, when highly electrified and so rendered especially vitalizing, has in recent times been distinguished by the name of ozone. This is one of the chief elements of a healthy atmosphere. Now, centuries ago it was known that certain plants acted as powerful disinfectants. Thus Herodotus tells us that, when in the second century the plague raged in Italy, the physicians recommended those who crowded into Rome to go to Laurentum, because there the sweet bay tree (*Laurus nobilis*) grew in great abundance, and the inhalation of air impregnated with its odors was a strong preservative against infection. And the disciples of Empedocles were wont to grow aromatic and balsamic herbs around their dwellings, from the belief that they were thus guarding themselves against fevers,agues and such like. Hae not, too, among us the tradition of its fever dispelling power given the name of feverfew to one of the strongest scented of the composite? Recent investigations, especially those of Prof. Montegazza, of Padua and Dr. Cornelius Fox, have shown that these old ideas were based on scientific truth. It is now ascertained that the quality of ozone is materially increased by the exposure to the rays of the sun of various plants, among which the most common are the lavender, musk, cherry, laurel, clove, fennel, narcissus, heliotrope, hyacinth and mignonette. It is interesting to know that the sunflower, which will grow almost anywhere, and could be turned to various useful purposes, is one of the most valuable of sanitary agents, since not only is it ozoniparus, but also destroys deleterious miasmata. It should be noted as a further proof of the good influence of plant culture on health, that while the manufacture of ozone is an independent work carried on by the flowers alone, the green leaves are performing their sanitary function by extracting carbonic acid gas from the atmosphere, and helping to reserve that proportion in its elements which makes it healthful. More remarkable perhaps than all is the eucalyptus, of which we have recently heard so much, and of which we shall soon know more. Thus the cultivation of flowers is a work not merely delightful and humanizing in itself, but one which, in a way most beautiful and picturesque, confers a positive benefit on society, so great that it can hardly be overrated, especially in large towns where there must necessarily be so much to poison and deteriorate the air we breathe. It may be added that the sunflower thrives even in the heart of London, and that it is readily propagated from seeds sown in March or April. It is nearly allied to the common Jerusalem artichoke, which grows in the remotest of districts.

Disease Germs.

Mothers know too well what is meant by the word "thrush" or "screw," that mouth malady which is so common with little children. To the profession it is known as an aphthous ulceration of the tongue, sphtha being the name of the disease, and signifying a hurting. The tongue "is swollen, tender and furred." There are excoriated spots, sometimes true ulcers, varying in size, perhaps, from that of a pin's head to that of half a pea, and these are severally capped with a white, curd-like mass. However diminutive these pustules may be, they are in truth hammocks of tiny plants, for each one contains many thousands of parasitic fungi, often called *torula*. These fungi attach themselves to the mucous membrane, and burrow among the epithelial cells. They are "composed of threads matted together like felt," whose basal ends intertwine among the epithelia, like the hair in the prepared mortar of the plasterer. At a recent meeting of the Academy of Natural Sciences, Prof. Leidy exhibited a mouse with little curdy patches on its ears, face and nose. Mr. Indifference would have passed the matter by as a stupid trifle; and a report of insipience escaped one of the wise men, who wished to know "what the mices was." However, little *Mus musculus* was regarded as an abnormal case, and a proper subject of scientific inquiry. The query was now, "What ailed the little fellow, and where had he been?" At this juncture the microscope spoke out in meeting, declaring with authority that the white spots were colonies of a parasitic fungus; and, strange to tell, they were as much like the thrush fungus as one pea is like its fellow in the same pod. The truth told, Mousie was captured in the children's department of Blockley hospital, where he had picked up the crumbs that had fallen from the mouth of a child patient. The diagnosis now seemed natural and direct. Mousie had been and got it—namely, the thrush—and, strange to say, he had got it bad, for it was on his ears and nose and face. Soon, in all probability, it would have entered the mouth, even if it had not already. A minute portion of one these white spots was subjected by skilled hands to a lens of very high power, and lo! there were the morbid parasites, tiny sporular bodies, some single, some double, and others "in chains of a dozen or more." The fungus was pronounced to be a *torula* or *oidium*, like that found in the disease known as thrush or sphtha. A drawing of it would be simply like a number of elongated heads strung together. But how diminutive these heads or cells were! A single one was 1-650 of a line in length, that is, it would take 7,650 of them in a line to make an inch.—Prof. Samuel Lockwood, in *Harper's Magazine* for May.

DOMESTIC ECONOMY.

How to Set a Table.

In answer to a question, a lady writer for the *New York Tribune* gives the following directions for "setting a table" and table etiquette generally. She writes: There is no arrier test of refinement in persons or families than the manner and style in which their food is served and eaten. Absolute and thorough cleanliness is the first requisite in the preparation and serving of food. Next to that may be placed taste and judgment in the arrangement of the table and the succession of courses. But, leaving all side issues, let us attend simply to the question in hand, "How to set the table." In the first place the sides of the table should be parallel with the sides of the room. It is simply distressing to a person with an eye to symmetry to have the table "askew." In the next place the tablecloth, which should be clean, white and nicely ironed, must be put on so that the middle of the cloth will be in the middle of the table and the folds of the cloth be parallel with the sides of the table. The plates are usually placed around the table and turned down to prevent any dust or other defilement from soiling them. Often, however, when they have been in the warming oven they are placed in a pile before the host, and after being served, headed to each guest. At the right of the plate, at right angles to the side of the table, is the knife, with the edge of the blade turned from the plate; parallel with that is the fork, with the tines turned down. The handles of the knife and fork are an inch or two from the edge of the table. Parallel with the edge of the table at the side of the plate opposite the guest is the spoon, with the bowl turned down. The napkin is sometimes placed at the right of the fork, sometimes on the plate, sometimes folded in fancy style and put in the goblet, but all the napkins on the table are in the same respective position. At the right-hand corner of the plate is a little butter receiver, of glass or of china, and a salt cellar. All the butter plates are in line, all the salts in line; so of the glasses or goblets, which are near the salts. In the center of the table is the center, or in its stead a vase of flowers or fruit. On one side of these stands the butter; on the other saucers in bottles, pickle and relishes. In the waiter at the end of the table occupied by the hostess, at her right, are coffee cups and saucers, at her left those for tea; the claret-basin and milk pitcher are at the left, the cream and sugar basin at the right. The tea and coffee are served in urns or pots and placed in front of the hostess. In this position they are not likely to burn the hands of the one at the right of the hostess. Bread is placed at the left of each plate, or laid on the plate, or nicely cut in slices and set on a bread plate at each end of the table. Soup is always served by the host. Fish is also served by the host, unless there are two kinds, when he serves the boiled fish and the hostess that which is fried. At the top of the table is placed the roast, at the bottom the stew. Where there is but one principal dish it is served by the host. If there are three, one is placed before him, the others opposite each other near the bottom of the table. Vegetables and other dishes occupy positions between the principal dishes. As each dish is set on a mat, and if for a time removed and returned to its place again, the table once properly set is easily kept in order till the repast is over.

Puddings and pie are generally served by the hostess. It is a good plan in teaching children and servants how to set a table to draw a diagram of the table with all the dishes in place and write down the names so that everything will be plain. Paste this on the inside of the closet door and then offer a suitable reward for perfect conformity of the table to this plan. The point to be made is uniformity in setting the table, that everything shall be precisely in its place every time. The very look of a well-set table is appetizing, and when, in addition to this, the air of the dining room is sweet, the walls are pleasantly decorated with pictures, the chairs are comfortable, the hostess is lovely, sweet-voiced and hospitable, the most languid appetite is stimulated and every sense is gratified. The table may be decorated with flowers or fruit, one or both. If there are neither, napkins of delicate tints relieve the white. They may be placed in the bread tray or the cake basket, though white is usually preferred. In some of the best families of the South, breakfast and tea are always served without a cloth, on a handsomely-polished mahogany or black walnut table. Under each plate is a napkin fringed and worked in cross stitch with scarlet cotton where the fringe ends. Mats of white crochet with scarlet edges, receive the dishes and contrast with the dark brightness beneath them.

CAULIFLOWER.—Soak the head two hours in cold salted water, and boil till tender in plenty of water. Have the water boiling when you put in the flower. Pour off the water and add a cup of cream or milk. Rub together a teaspoonful of butter and a large spoonful of flour. Stir into the milk, season as you like, and let all boil up together for five minutes and serve.

OAT MEAL AND GRAHAM GEMS.—Mix equal parts of fine Irish oat meal and graham flour into a thick batter with milk and water equal parts, fill hot gem irons and bake with a brisk heat. Very sweet and tender.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Volatility of Gold and Silver; The O'Hara Chloridizing Furnace, 305. The Inter-Yubas Ridge; Schofield's Sulphuret Concentrator; The Centennial, 312. Pay Chutes in the Comstock Lode; The Opening of the Centennial Exposition, 313. Virginia City and Comstock Mines; Patents and Inventions, 316.

ILLUSTRATIONS.—The O'Hara Chloridizing Furnace, 305. Pay Chute in the Comstock Lode, 313.

MECHANICAL PROGRESS.—Mechanical Specialties for the Centennial; A Lightning Box Machine; American Machinery for Siberia; A New Gun; A Novel Hoisting Crane; French Steam Wagon; An Old Engineer; Weakening Rails by Drilling and Punching, 307.

SCIENTIFIC PROGRESS.—A New Test Proposed for Arsenic; Artificial Light Made Sensitive to Light; New Substitute for Gold; New Method for the Quantitative Analysis of Silver; Atmospheric Changes and Fire-damp; Bounds of Microscopic Investigation, 307.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 308.

MINING SUMMARY from various counties in California, Nevada and Idaho, 308-10-16.

THE ENGINEER.—Channel Schemes; A New Bridge Proposed Across the St. Lawrence, 310.

USEFUL INFORMATION.—Gliding on Exposed Ironwork; How to Make a Good Scarecrow; Novel Cork Leather; Uses of Mustard Seed Oil, 311.

GOOD HEALTH.—The Sanitary Side of Soap; How Vegetation Affects Health; Disease Germs, 311.

DOMESTIC ECONOMY.—How to Set a Table; Bird-were; Cat Meat and Graham Gems, 311.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 316 and other pages.

MISCELLANEOUS ARTICLES.—At the University; New Sulphurets Concentrator; Mining Suits; James G. Fair on the Silver Question; Coinage at the Mint; Butte County Mines; Borax Lake, 306. Naming the Mines, 310. The Famous Amargosa Gold Mine, 314. Steam Pumps and Fuel, 318.

NEW ADVERTISEMENTS.

Sulphuret Concentrator, Schofield Concentrating Co., S. F.; A. L. Fish & Co., Dealers in Machinery, S. F.; Amador Canal and Mining Co.—Assessment.

It is said that there are peculiar circumstances attending the terrible explosion in Bergen tunnel Saturday night which point to strikers as the perpetrators of the fiendish deed. Out of 600 men employed there are 550 on a strike. The strikers made a demand for increased compensation on Saturday, but only a partial concession was made. Mr. McIntyre, one of the bosses, says the strikers are a branch of the "Molly Maguires," and he can prove it. The theory of the police as regards the explosion is of a similar character. They think the strikers had placed cartridges or fuses in the building. No direct evidence has been found against the strikers. The injury to Jersey City will be about \$350,000; Hoboken, \$150,000.

Six of the largest print mills in Massachusetts and Vermont have failed, with liabilities aggregating over a million of dollars. They ran in all over 1,000 looms on print goods. Some 800 people have been thrown out of employment. The failure has created much stir among commission merchants in New York, several large houses being heavily involved.

The Mechanics' Institute has elected W. P. Stont, J. R. Wilcox, B. H. Freeman, J. H. McDonald and D. R. Coleman, a committee to nominate Trustees. They are to report on Saturday, June 3d. The election comes off on June 5th.

CITY AGENT.—Mr. E. B. Hopkinson is our authorized agent for receiving subscriptions in San Francisco.

The Inter-Yubas Ridge.

It would be difficult to find an area of territory that has produced so large a number of profitable gravel claims as that lying between the South and Middle Yubas, extending from French Corral upwards for some 15 miles to North Bloomfield, in Nevada county.

This region covers an area of about 50 square miles, and lies in the townships of Bridgeport and Bloomfield, and may justly be regarded as one vast bed of auriferous deposits. From incidental causes the year 1875 was an exceptionally poor one, yet the "ridge" is reported as producing about one million and a quarter in gold dust. South and north of it, running in canons 1,000 feet deep, the classic North and Middle Yubas rattle along over their gritty beds of gravel and boulders. Very different are they to-day from what they were as seen by the Argonauts of '49. Then, fed by the snows of the Sierras and the streams of the hillside, their limpid currents rolled sweetly on in a deep and crystal tide—to-day with their sources cut off by a hundred ditches and sluices, they appear, even in winter, as turbulent but muddy and insignificant streams—leaping with break-neck speed from boulder to boulder, bearing with them the inevitable "sickens," which so badly "sickens" the ranchman far below.

Two hundred and fifty miles of ditches now convey the waters that once drained into the Yubas, "Over hill, over dale, through the brush, through the briars," across deep cuts and high flumes, to supply the miners along the way with the indispensable aid in securing their treasures. Among the more important operations carried on in this region are the mines of the American company, the Milton company, the Bockeye company, the Badger Hill company, the Consolidated mining company, North Bloomfield company, Union gravel company and a score of others.

As would be expected, all along the ridge, contiguous to the principal mines, are to be found a number of villages with populations ranging from 500 to a score. The most important of these little towns is North San Juan, which contains several fine stores, a banking establishment and a weekly paper—the *Times*. This last is a popular, wide-awake sheet, edited by Judge O. P. Stidger, a well known lawyer. French Corral is a famous mining town, a few miles below San Juan. The principal owners here are the Milton company, who conduct very extensive operations and own mining property of immense value. Last year this company shipped almost \$200,000 in gold. The American company, near San Juan, is another very prosperous corporation. This company is at present running a new 4000-foot tunnel, which, when completed, will add vastly to the value of its claims. No less than 52 modern currents are operated in these works. The corporation is very popular, as it mostly consists of residents of the neighborhood and employs only white labor.

All along from French Corral to San Juan the bottom of the detrital deposits is no less than 900 feet above the level of the river. Because the lower parts of these deposits consist of granite, quartz and the metamorphic rocks of the Sierra Nevada, cemented together in a compact mass, and often of a bluish color, this hydraulic belt is often confounded with the "Great Blue lead." In fact, however, this and other deposits in this neighborhood are a continuation of a Sierra county river bed, which runs parallel with the Blue lead, the latter running several miles eastward of the former, from Snow Point to Yon Bet, and thence through Placer county.

Cherokee stands on the verge of a plain of auriferous soil containing no less than 3,000 acres. In the early days this proved literally a "gold mine" to surface placer miners. It is yet very rich, but for the most part worked out of grade. The bedrock in some places is so deep that no shaft has yet been sunk to reach it. Recently the Milton company have procured interests here to the amount of \$83,000. We believe they propose to shortly run a snail-like outlet by way of tunneling to the Middle Yuba. In Doolittle's charts this flat appears as an ancient river "overflow," but its course so far has not been very well defined. Several smaller claims in this neighborhood are worked on a paying basis.

From Cherokee to North Columbia, a distance of some four miles, extends a chain of very rich mining claims, the Consolidated company holding a just prominence in the energy and skill which stamps all its operations. Its monitors and methods of application, if not the best in the State, are certainly among the best. Indeed, to a tourist anxious to see the "Niagara" of hydraulic mining, we would say, "go and see the monitors of the Consolidated mine at North Columbia." It is impossible for one who has not witnessed it to form a correct idea of the effect produced by a 200-foot pressure forcing an enormous torrent of water against these gravel precipices, which seem to actually melt away at its icy touch.

There are other operations in this locality also well worthy of special notice, which we cannot notice in this article; and further on, the North Bloomfield gravel company and others carry on very important and withal profitable operations.

Traveling from San Juan to Moore's Flat is to ascend from the foothills to the Sierras, and

yet the grade, for the most part, is so gradual as to be hardly perceptible. In the absence of the barometer, it is only by the change in the climate that we can tell how great a difference is produced by so short a distance as 16 miles. In San Juan the snow seldom lies on the ground longer than 24 hours, while at Moore's Flat they have continuous snow to the depth of 10 or 12 feet for four or five months in the year. As may be expected, the "Moore's Flatters" are no "flats" when it comes to running on snowshoes.

Besides the gravel mines there are several fine ledges of quartz running through the Inter-Yubas ridge. Owing to the Fryer process excitement, there have been a large number of quartz claims located within the last few months. Gravel miners, however, "don't go a cent" on quartz, and ridicule their brethren of a harder fancy. Of one thing, however, there can be no doubt: if the Fryer process is the success it affects to be, then this ridge will prove far more valuable for quartz mining than it ever did for deep placer, and that is saying a great deal.

The prospect for the coming summer is better than it has been for years. An abundance of water and plenty of "pay dirt" are here, and these are the elements of success to the rollicking hydraulicers.

Schofield's Sulphuret Concentrator.

The subject of "sulphurets" is one of vital importance to the miners of this coast, as in a large proportion of mines the saving and working of the sulphurets determines the question of profit or loss in the venture. This being the case, great attention has been paid by metallurgists to appliances for saving the sulphurets as well as processes for working them. The most important of these subjects is naturally that of saving the sulphurets, which are scattered in minute particles through a large quantity of ore. As the sulphurets will not amalgamate, the process of concentration has to be resorted to. This may be called a science in itself. The great number of different machines which have been invented for effecting it is sufficient proof that it is not in all cases an easy task to accomplish.

All apparatus for the purpose is essentially based upon the fact of the different specific gravities of the substances to be separated. This would seem at first glance to be a very simple affair, but it is not, by any means. The great variety of size and shape complicates the problem. Particles of different specific weight, but of the same actual weight, will, if of the same shape, go together. But the difficulty in the way of constructing a perfect concentrator is that there are so many differences in size and shape in the same gangue. The presence of the slimes also seriously complicates the problem and is an item to which sufficient attention has not hitherto been given. The steps in a perfect concentration are, first, the entire separation of the slimes from the granular matter; second, the sorting of the various particles, and lastly, the concentration of the sulphurets from the sands. Volumes have been written on the subject, innumerable experiments tried, and a multiplicity of mechanical devices constructed to effect a perfect concentration.

The latest device for this purpose which has come to our notice is the "Schofield sulphuret concentrator," a California invention which is just now being brought prominently before the mining community. We examined two of these machines this week, which are being built for the Oneida mining company, Amador county, and the plain description which we give can be readily understood by mining men.

The concentrators are quite simple in construction and operation, there being no complicated machinery about them at all. They are constructed mostly of wood, and consist of two or more hopper-shaped boxes placed over a tank with four compartments, and as many small sluices three or four inches in width and 60 feet in length, leading from the above tank to another below, which latter is divided into two compartments. A few inches above the real bottom of the hopper-shaped boxes is a false bottom, composed of a screen of perforated sheet iron, beneath which is inserted a pipe conveying clean water from a tank above with at least 10 or 12 feet pressure. Immediately over and close to the false bottom are three perforated pipes through which the main portion of the water passes. A steady upward stream of water passes from these perforated pipes with sufficient pressure to prevent any light and worthless matter from passing downward through the screen against the upward current. The pipe under the screen is for throwing fine upward streams against the false bottom to prevent any chance of packing and closing the perforations. Moreover, a stream from this lower pipe can be turned on over the collected material at the bottom to prevent packing and aid in discharging the sands.

The pulp is conveyed from the battery through a sluice into the top of the first box, and all the coarse heavy sand and most of the sulphurets pass down through the screen and out through the discharge cocks into the tank below, but all sand and sulphurets which are too fine and light to resist the upward current

of water in the first box, pass on into the next box, and go through the same trial again under a diminished pressure of water, which results in abstracting a finer quality of sand and the remainder of the sulphurets. The quicksilver and amalgam stops in the bottom of the first box. Quicksilver is placed under the false bottom of both boxes, in order to collect any particles of gold or small grains which may have passed the ordinary mill process. The slimes are separated and pass over the edge of the box with the waste water, thus being one of the most important features of this concentrator, and one generally overlooked in previous machines.

When one or more apartments of the tank beneath the boxes are filled with sand, plugs are removed, which let the sand flow into the small sluices, and a small stream of water is applied, which, with the sand, forms gentle undulations or sand riffs, which continually work the sulphurets down to the bottom, but carry the sand out at the end of the sluice over the lower tank. When all is out of the upper tank which will conveniently flow out, the plugs are replaced and the stream of clear water continued until the sand is all washed out of the sluices; the sulphurets are then carried by a stronger current and let out through a gate in the bottom of the last sluice into the tank below.

It will be seen from what has been said, that this machine effectually separates the slimes from the sand at the very first operation, none of them ever getting even into the first tank under the hopper-shaped boxes. By graduating the flow of water from the perforated pipes over the false bottom, advantage may be taken of the very slightest difference in specific gravity of the particles in the material under treatment. The sluices are narrow and deep, and when closing up a clear stream of water may be sent with more or less force through the sluices and drive off all the lighter portions, leaving the sulphurets perfectly clean.

This apparatus requires no power whatever, the only thing necessary being the amount of water which will pass an inch and a half pipe under a twelve foot head. There being no motion or complicated machinery, there is no perceptible wear or tear, and the appliance will last for years. The first cost is comparatively small, and the labor and expense of running is very light, one man being able to attend to it for a twenty-stamp mill. It answers the purpose, as well as a sulphuret concentrator, of saving what gold and amalgam escapes from the battery. The manufacturers claim that it saves a larger percentage of valuable material from the sands than other machines, and offer a guarantee of saving ninety per cent. of the sulphurets contained in the rock.

Although Schofield's sulphuret concentrator has been in use in several places in California for over a year, it is only now becoming well known. The inventor has preferred to give it good practical trials before endeavoring to introduce it extensively, and judging from the strong testimonials obtained it has been entirely successful.

We refer to the advertisement on page 317, for testimonials containing the names of the various mills where it has been in use, and the opinions of the superintendents, so that parties interested in it can write to those who have used it practically, and obtain whatever further information may be desirable. The office of the Schofield concentrator company is room 59, Nevada block, in this city.

The Centennial.

The stirring event of the week throughout the whole country is the opening of the grand display at Philadelphia, of which we present a telegraphic report in another column. The report tells us that the President of the United States turned on the steam which set 14 acres of machinery in motion. It is a grand thought. It stirs the blood to think of such an expanse of useful machinery sounding the note of industrial and mechanical progress. But need we go to Philadelphia to gain material for a stirring thought? No. Right at our doors, in our magnificent grain fields, will soon begin a motion of valuable machinery, which, if we collect into a single thought the thousands of our harvesters and the varied machines they employ, will far surpass the figures of the Philadelphia action, whether the computation he made in trial and mechanical progress. Yes, we are content that the nation should revel in the grandeur of the industry symbolized in Philadelphia. We are proud of it, too, and we are doubly happy in the year. Whi amid the hardship and depression at the East, (which we most sincerely deplore), they are looking toward Philadelphia, if perchance its occasion may cast some enlivening influence upon their clouded industries, we, from out the grandest prosperity and promise, look abroad upon the coast, and in the activity here displayed, see reflected all the life and industry which fills those Eastern halls. The Centennial is advanced as an occasion for rejoicing. We have then two Centennials, one here, the other in Philadelphia.

The managers of the direct United States cable announce that no increase will be made in the rates charged to the public or press. The interruption of the Anglo-American cables has greatly increased the volume of business over the cable of the direct company, but business is being transmitted as promptly as possible.

Pay Chutes in the Comstock Lode.

EDITORS PRESS:—Permit me in your columns to call the attention of the mining community to the important question of the distribution of the valuable minerals in lodes bearing gold and silver. To illustrate my ideas I have prepared the illustration given herewith from a diagram on Parkinson's map of the Comstock lode, showing a vertical section of the lode, drawn on a scale of 1,200 feet to one inch. The proportions may not be observed accurately, but precision is not necessary for my purpose. The top line represents the elevation of the ground on the line where the lode comes to the surface. The bottom line is about 2,400 feet below the surface, and the marks on it are intended to indicate the limits of the separate mining properties, which, beginning at the north, appear in the following order as numbered on the diagram:

MINES.	LENGTH IN FEET.
1 Ophir.....	675
2 California.....	600
3 Consolidated Virginia.....	710
4 Best & Belcher.....	636
5 Gould & Curry.....	617
6 Savage.....	771
7 Hale & Norcross.....	400
8 Chollar Potosi.....	1400
9 Bullion.....	943
10 Eschschuer.....	400
11 Alpha.....	306
12 Imperial-Empire.....	685
13 Yellow Jacket.....	357
14 Keweenaw.....	93
15 Crown Point.....	541
16 Belcher.....	1008

The white lines running down are the shafts and inclines by which the veins have been opened. The lighter spots in the vein indicate the places where the rich ore has been found;

the direction in which they may hup to find another pocket.

12. The wider and richer the lode, the longer horizontally are the pay chutes as a general rule. The main measure of the size of a pay chute is its horizontal length. All pay chutes in fissure lodes run down to a depth beyond the reach of practical working.

13. The chief business of the gold and silver miner is to find and follow pay chutes.

14. The money spent in exploring lodes outside of the pay chutes gives no return.

15. Many millions have been so spent in the Comstock lode.

16. All the dividends of the Comstock lode have been paid by three pay chutes, each nearly half a mile long horizontally, with barren intervals of a third of a mile between them horizontally, and half a mile vertically.

17. One of these pay chutes has produced \$50,000,000, one \$80,000,000, and the third may be set down with past production and ore in sight for at least \$350,000,000.

18. Each pay chute has mineral or chemical peculiarities distinguishing its ores.

Although we have repeatedly mentioned this theory of pay chutes in the *Alta* and called public attention to it, yet it has been passed over as if there were no facts to support it, and mining superintendents and engineers generally seem to attach no importance to it; and they make their plans, run their shafts, tunnels and drifts, and spend their money as if there were as much probability of finding ore in one part of the vein as in another, even after the situation and direction of pay chimneys have been well determined.

In the second annual report of the Commission of Mining Statistics for the year 1867, (submitted to the Secretary of the Treasury in March, 1868,) mention is made of pay chimneys in the following gold mines in California, viz: The Pina Tree, Coward, Marble Spring, Goodwin and Mary Harrison, in Mariposa county; the App, Soulsby, Platt, Mt. Vernon,

The Opening of the Centennial Exposition.

We have received by telegraph on Wednesday, the 10th instant, quite a detailed report of the successful opening of the Nation's Grand Centennial Commemorative Exhibition at Philadelphia.

The gates were opened a little after 8 o'clock, and crowds continued to pour in until it was estimated that 50,000 people were on the grounds. The ceremonies opened at precisely 10:15 A. M., the national airs of all nations being performed by a large orchestra.

A spacious platform had been erected at the side of Memorial hall, north of the center of the building. Seats were arranged on the platform for officials and other invited guests. At the right of the center were seats for the President of the United States and members of the Cabinet, and further to the right seats of the United States Senators and members of the House of Representatives, Governors of various States, etc. On the left center were seats of the United States Supreme Court, and further to the left, seats for the Diplomatic Corps and members of the Centennial Commission, Board of Finance, Woman's Executive Committee, Foreign Commissioners, Mayor, Council and other officials of Philadelphia; Mayors of other cities, State Centennial Boards, Boards of Awards, Judges, yacht and rifle clubs, and along the front of the platform were seats for members of the press. The orchestra of 150 pieces, and chorals of 1,000 voices, under the direction of Theodore Thomas and Dudley Buck, were stationed directly in front of the platform.

As the Emperor of Brazil and party came to the platform they were loudly cheered, and the orchestra played the Brazilian national hymn.

At 10:45 the signal was given for the music to stop, and five minutes later the President, escorted by General Hewley, advanced to the

appropriate upon this Centennial occasion to bring together in Philadelphia, for popular inspection, specimens of our attainments in industry, the fine arts and literature, science and philosophy, as well as in the great business of agriculture and of commerce, that we may the more thoroughly appreciate the excellencies and deficiencies of our achievements and also give emphatic expression to the earnest desire to cultivate the friendship of our fellow members of this great family of nations. The enlightened agricultural, commercial and manufacturing people of the world have been invited to send thither corresponding specimens of their industries to exhibit on equal terms in friendly competition with our own. With this invitation they have generously responded. For so doing they have our hearty thanks. The beauty and utility of the contributions will this day be submitted to your inspection by the managers of this exhibition. We are glad to know that a view of the specimens of skill of all nations will afford to you unequalled pleasures, and yield to you a valuable practical knowledge of so many of the remarkable results of the wonderful skill existing in enlightened communities. One hundred years ago our country was new and but partly settled. Our necessities have compelled us chiefly to expend our means in felling the forests, subduing the prairies, building dwellings, factories, ships, docks, warehouses, roads, canals, machinery, etc.; most of our schools, libraries and asylums have been established within 100 years. Burdened by these great primal works of necessity which could not be delayed, we yet have done what this exhibition will show in this direction and rivaling the older and more advanced nation, in law, medicine and theology, in science, literature, philosophy and the fine arts.

Whist proud of what we have done, we regret that we have not done more. Our achievements have been great enough, however, to make it easy for our people to acknowledge superior merit wherever found.

VERTICAL SECTION OF COMSTOCK LODGE, SHOWING DISTRIBUTION OF ORE, PAY CHUTES AND BARREN PORTIONS.

the darker streaks, including the light spots, are what I regard as the pay chutes, that is, the only places where large bodies of ore will probably be found; and the black portions are the barren chutes in which there is little probability of finding ore. This theory of pay chutes, the origin of which is unknown to me, was thus referred to in an editorial published several months ago:

1. The veins of every rich auriferous or argentiferous fissure lode is partly gangue, or barren rock, partly pay ore.

2. The pay ore is not scattered about in the lode without system.

3. The use by miners of the terms "pay chutes" and "pay chimneys" is not accidental or unmeaning, but is the result of long experience.

4. The French word "chute," meaning literally a "fall" or steep channel, is the equivalent of chimney, and the two words are suggested by the fact that after the rich ore has been taken the hollow places are like the flue of a chimney.

5. A pay chute is a streak in the lode running down usually at an angle of not less than 30 deg. to the horizon.

6. There may be, and there usually is, much barren rock in a pay chute, but there is no large body of rich ore outside of it in a fissure lode.

7. A rich lode that has been well explored for more than half a mile usually shows more than one pay chute.

8. The pay chutes in the same lode dip in the same direction and at the same angle, and are approximately of equal size.

9. If the sides of the lode show streaks or scratches, as if the veins had been pushed upward between the walls, those scratches indicate the direction of the pay chutes.

10. There are pay chutes in pocket lodes as well as in milling lodes. A pocket lode is one in which the gold is found in small clusters, so rich that much of it may be separated from its quartz in a hand mortar; whereas milling lodes are those in which the metal is scattered evenly through a large mass of rock and cannot be extracted profitably without a mill.

11. Some of the "pocket miners" in the pocket mining districts, such as Bald mountain, Tuolumne county, and West Point, Calaveras county, when they find a rich pocket, near the surface, if they think it worth their trouble to sink, examine the scratches and run their incline down with them, as a guide for

Sophia and Draper, in Tuolumne; the Bovee, Woodhouse and Crispin, in Calaveras; the Hayward, Onside, Lincoln, Tellurium and Crafts, in Auer; the Pacific, in El Dorado; the Banner, in Nevada; the Sierra Buttes and Independence, in Sierra, and the Crescent in Plumas county; and of these mines one is represented to have seven pay chutes; two each six; two each five; and the 23 mines together have 54 pay chutes. Reference is not made to that report as proof, for it was based on a hasty reconnaissance, but it indicates where evidence can be obtained either to establish or overthrow our theory, and we suggest to mining engineers and superintendents, miners and mine owners, the importance of making careful vertical diagrams of their workings, showing the position of their pay ores. Such diagrams would doubtless be published without charge by the MINING AND SCIENTIFIC PRESS, and a collection of them would, we are satisfied, be of great service to educate the mining community.

As the finding of ore is the chief talk of our mining industry, I think that you will agree with me that this theory of pay chutes deserves more attention than it has yet received, and that it is very desirable to have diagrams showing the distribution of the ore in all our valuable mines. I am convinced that our miners and mining engineers have much valuable information relating to pay chutes never heretofore published. Can it not be drawn out?

JOHN S. HITTALL.

San Francisco, May 8th, 1876.

VERDICT AGAINST A MINING COMPANY.—At Carson, Nevada, this week, in the United States circuit court, a verdict was rendered for \$20,000 in the case of Mary Jane Williams, administratrix, against the Newark silver mining company, a corporation doing business in Nevada. This action was brought by Mrs. Williams to recover damages for the killing of her husband in the Newark mine, in July, 1874.

GENERAL CROOK has taken the field in person for his campaign against the Indians, Sitting Bull, Crazy Horse and the rest of the fighting Sioux. It is probable that the Reynolds band of soldiers will be sent to the rear this time, and we may expect to hear of lively times in the Indian country during the summer months.

It is reported that the Indians near Fort Pierre attacked a Black Hills train and killed and scalped a number of men. The report needs confirmation, but it is regarded as probably true.

front of the platform and was loudly cheered. The orchestra then played "Hail to the Chief," during which time the President shook hands with the Emperor and the Emperor's guests.

At 11:30, Wagner's Centennial Inauguration March was performed by the orchestra. At the conclusion of which Bishop Simpson offered a prayer, during the rendering of which a majority of the vast assemblage stood with uncovered heads.

At the conclusion of Bishop Simpson's prayer, Whittier's hymn was sung with grand effect, eliciting loud applause. It is as follows:

Hymn by John Greenleaf Whittier.

Our fathers' God, from out whose hand
The centuries fall, the grains of sand,
We meet to-day, united free,
And loyal to our land and Thee—
To thank Thee for the era done,
And trust Thee for the opening one.

Here, where of old by Thy design
The fathers spoke that word of Thine,
Whose echo is the glad refrain
Of rended bolt and falling chain,
To grace our festal time from all
The zones of earth our guests we call.

Be with us while the New World greets
The Old World, thronging all its streets;
Unveiling all the triumphs won
By art or toil beneath the sun,
And unto common good ordain
This rivalry of hand and brain.

Thou who hast here in concord furled
The war-flag of a gathered world,
Beneath our Western skies fulfill
The Orient's mission of good will,
And, freighted with love's golden fleece,
Send back the Argonauts of peace.

For Art and Labor met in truce,
For Beauty made the bride of Use,
We thank Thee, while withal we crave
The austere virtues, strong to save,
The honor, proof to place or gold,
The manhood never bought nor sold!

O make Thou us through the centuries long
In peace secure, in justice strong;
Around our gift of freedom draw
The safeguards of Thy righteous law,
And, cast in some diviner mold,
Let the new cycle shame the old.

After the singing of the opening hymn, Mr. Welch, President of the Board of Finance, presented the buildings to the United States Commission in an appropriate address. General Hewley, President of the Commission, followed in an address, and closed by presenting the exposition to the President of the United States. Then followed

The Address of President Grant:

My Countrymen: It has been thought ap-

propriate upon this Centennial occasion to bring together in Philadelphia, for popular inspection, specimens of our attainments in industry, the fine arts and literature, science and philosophy, as well as in the great business of agriculture and of commerce, that we may the more thoroughly appreciate the excellencies and deficiencies of our achievements and also give emphatic expression to the earnest desire to cultivate the friendship of our fellow members of this great family of nations. The enlightened agricultural, commercial and manufacturing people of the world have been invited to send thither corresponding specimens of their industries to exhibit on equal terms in friendly competition with our own. With this invitation they have generously responded. For so doing they have our hearty thanks. The beauty and utility of the contributions will this day be submitted to your inspection by the managers of this exhibition. We are glad to know that a view of the specimens of skill of all nations will afford to you unequalled pleasures, and yield to you a valuable practical knowledge of so many of the remarkable results of the wonderful skill existing in enlightened communities. One hundred years ago our country was new and but partly settled. Our necessities have compelled us chiefly to expend our means in felling the forests, subduing the prairies, building dwellings, factories, ships, docks, warehouses, roads, canals, machinery, etc.; most of our schools, libraries and asylums have been established within 100 years. Burdened by these great primal works of necessity which could not be delayed, we yet have done what this exhibition will show in this direction and rivaling the older and more advanced nation, in law, medicine and theology, in science, literature, philosophy and the fine arts.

Whist proud of what we have done, we regret that we have not done more. Our achievements have been great enough, however, to make it easy for our people to acknowledge superior merit wherever found.

After the address of President Grant the "Cantata" of Mr. Lanier was rendered with fine effect.

After the ceremonies in the memorial hall, the line of march was taken to the machinery building. President Grant opened the valve of the great Corliss engine and the whiz and whirl of 14 acres of machinery sounded the refrain to the cadences of the orchestra and the periods of the orator and the exposition began its course.

OF INTEREST TO CORPORATIONS.—Section 299 of the Civil Code, as introduced and amended by the last Legislature, reads as follows: "No corporation hereafter formed under the provisions of this chapter shall purchase, locate, or hold property in any county of the State, without filing a certified copy of the certificate of its articles of incorporation in the office of the County Clerk of the county in which such property is situated, within 60 days after such purchase or location is made; and every corporation now in existence must, within 90 days after the passage of this Act, file a certified copy of the certificate of its articles of incorporation, as provided in this section; and a certified copy of such copy shall, as evidence, have the same force and effect as a certified copy of the original. Any corporation failing to comply with the provisions of this section shall not maintain or defend any action or proceeding in relation to such property." This law went into effect on the 3d of April, and so far but two corporations have complied with its provisions.

ANOTHER outbreak is feared in the Massillon, Ohio, coal mines, in consequence of some of the strikers having gone to work at the offered wages. The State militia are protecting the workmen, but the strikers are awaiting their chance.

The Famous Amargoza Gold Mine.

We copy the following from the Eureka Sentinel of the 29th inst:

The story of the famous "Amargoza" gold mine, discovered about 20 years ago by a party of emigrants on their way to California by the southern route, is familiar to nearly every one on the Pacific coast. The magnificent specimens brought to San Francisco by the emigrants created great excitement at the time, but the emigrants kept the secret to themselves, and, fitting out a company, started back to their treasure trove, and that was the last heard of them until months afterwards, when it was ascertained that the party had been surprised and murdered by the Indians. Party after party has been organized, and thousands of dollars expended in searching for the "Amargoza," but all have proved unsuccessful, until a small prospecting party came upon the mine by mere chance, and no doubt under the same circumstances that led its first discoverers to its hiding place. Death valley has at last divulged its secret, and the famous Amargoza has been rediscovered. The party who found the mine was composed of J. B. Osborne, the well known mining operator of this place, and his partners, Messrs. Hassan, Phillips and Black. Mr. Osborne returned to town Thursday night, and yesterday, in a brief conversation, related to us the discovery they had made. The Amargoza is situated in a solitary mountain near the center of the southern border of Death valley, almost the last place in the world a prospector would seek for gold. It is situated in San Bernardino county, California, close to the old emigrant road. A mill had been erected on the grounds, but was destroyed by the Indians. Four adobe houses and several of stone still remain on the ground. The party made an examination of the mine, passing through the various tunnels made by the emigrants and taking out some of the rock, which proved to be red quartz, and although without the proper appliances for thoroughly testing it, they succeeded by "horning" in obtaining the most satisfactory results. A team will arrive in town in a day or two with specimens from the mine for assay. Mr. Osborne and party have located the lode and have already started work, and intend to send a sufficient number of men there to put the mine in proper working shape. Mr. Osborne has promised to give us the full details of the discovery of the mine next week. During their prospecting tour they also located a number of mines in Resting Springs district, which is also in San Bernardino county, and 25 miles from the Lincoln county line. The mines in this district show an immense body of carbonate ores and Mr. Osborne assures us that the country is the most promising he has ever seen, and the facilities for working the mines and the transportation of bullion, etc., unequalled. We anticipate a rush to that section this summer.

THE O'HARRA CHLORIDIZING FURNACE.

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1500 lbs of salt at 1 1/2c.....	22.50
Wear of shoes and power.....	1.50

Cost for 15 tons.....	\$14.00
Cost for one ton.....	2.93 1/3

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

BERRY & PLACE,

San Francisco,

Are the only Agents for sale of these Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.) Our new Mining Engine is built from plans and specifications of several of our most successful mining engineers, and the result is the most complete

Double Drum Hoisting Engine

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Can. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

BERRY & PLACE,
(Successors to Treadwell & Co.)

NEW ASSAY OFFICE.

Thomas Price (formerly of the San Francisco Assaying and Refining Works), having fitted up the old Pacific Mail building, No. 524 Sacramento street, corner of Leidesdorff, as an Assay Office and Chemical Laboratory, is now prepared to make assays of the precious and useful metals and their ores, as well as complete or partial analyses of all minerals, salts, waters or other substances that may be desired.

His office will be opened for business on Monday, May 1st, and he hopes that his long residence and experience in his profession will entitle him to a reasonable portion of the business of his friends and the public generally.

Patented May 12, 1873.

USE NO OTHER, AND INQUIRE FOR THESE GOODS ONLY. eow-bp

SEWING MACHINES.—We have a first-class machine we wish to dispose of on favorable terms. Apply at this office.

(Continued from page 310.)

ELY DISTRICT.

HEAVY MACHINERY.—Eureka Sentinel, May 4: The Meadow Valley company at Ploche is having shipped some of the finest and heaviest machinery that has ever been used by any mining company in Eastern Nevada. The whole weighs upwards of 300,000 pounds. We noticed at the depot yesterday a shaft 15 inches in diameter and 18 feet in length, which weighed 10,000, and a portion of the engine frame, weighing 13,000. There are 60,000 pounds now at Palsade awaiting shipment.

EUREKA DISTRICT.

EUREKA CONSOLIDATED.—Eureka Sentinel, May 6: The stone work for the foundation of the new hoisting at the Lawton shaft, is completed, and the mechanics are busily engaged putting the machinery in place. It is expected that the work will be in running order by the 15th inst. It will require a few days to hoist the water out of the shaft, and active operations in the mine will commence about the 20th. The few repairs necessary on the company's railroad are being made, and everything will be in readiness for the transportation of ore by the time work is commenced in the mine. The furnaces will start up as soon as there is ore enough ahead to insure their continuous running.

The Atlas.—The fires were started in one of the furnaces at the Atlas yesterday, and the smelting of ore will commence this morning. The other furnace is undergoing repairs and will be put in operation as soon as completed. The works are under the superintendence of A. Arents, an experienced smelter, who, in the early days of Eureka, had charge of the Consolidated furnaces.

NEVADA DISTRICT.

GOON ORE.—White Pine News, May 6: A few days ago we were shown some very rich ore from the Champion mine, in Nevada district, which is situated about half way between Mineral City and Ward district. The Champion mine is owned by George W. Dale and Isaac Hand, who are now selling very grand with their prospects in opening the lead, and are well convinced that they have a bonanza. The ore we saw had been sent here to be assayed, and was said to be a fair sample of the lead, which would assay \$250 or \$300 per ton.

Idaho.

WAGONTOWN MINES.—Cor. Owyhee Avalanche, April 24: There is one notable fact pertaining to the prospects here: There is a great deal of very rich and heavy float on the surface that has come from mines not yet discovered. The coming season will reveal a great many more rich mines in this district if there is enough life left in the country to do a little prospecting. The great necessity of the camp is reduction works. We need at least two mills—one of them to work by the roasting process. We are greatly in hopes that some one will be long embrace the opportunity of making a fortune for himself while he is serving the community, by the erection of mills, to work these ores. The majority of the mines are not rich enough to warrant the owners to haul 10 miles up hill to get their ore crushed. Fine mill sites are all along Jordan creek, and the farthest mines off are not more than a mile and a half from the creek. There is some poverty in the camp in consequence of the numerous failures and great stagnation during the past winter, that but few of those who have made valuable discoveries here are able to take out a large quantity of ore until there are crushing facilities in sight. William Oglesby has sold to Doctor Peters 100 feet in the Henrietta mine for \$2,000 (\$20 per foot), one-fourth down and three-fourths on time. Note secured by mortgage for the unpaid three-fourths.

Virginia City and Comstock Mines.**NUMBER TWO.**

[By our Resident Correspondent.]

While the mines of the Comstock have been the theme of many a pen in reports, essays and letters, scientific, mechanical and historical, while they have been visited by thousands of sight-seers and some votaries of science, and while they have added millions upon millions to the world's gold and silver, there is still, a marvelous ignorance of their actual condition and a want of appreciation of and sometimes disbelief in their magnitude. That this is true of the English capitalists who are most attracted by mining investments, admits of no doubt, for while they have invested largely in other States and Territories, and even in other portions of this State, they have but little interest here. In New York the feeling of interest may be said to have only begun, and is yet almost confined to speculations in the stocks. If intelligent capital everywhere was fully informed of the developments that have been made here in the last five years, it is hardly possible that so many of the (as yet) lesser claims should make such slow progress in prospecting, in many instances having as good indications now as had some of the million producing mines a few years since. There is much need of this information in some convenient form, readily accessible to a large class of persons who would be benefited by it and whose knowledge thus gained would materially benefit the mining interests. It is of course a work of time and laborious effort, and needs as a chief requisite, the confidence and co-operation of the officers of the mining companies and the owners of undeveloped claims. With this secured, no doubt the labor would be cheerfully performed, and it is believed that a record of the results in the MINING AND SCIENTIFIC PRESS would form a valuable guide and directory to this wonderful district.

A glance at the latest map of the Comstock and its surroundings shows

A Large Number of Mining Claims

East of the north end of the ledge. And it is here, among these mines less known to the public than those which are older and more developed, that we propose to begin. Almost every inch of this ground is located, and the claims cross, interlace and overlap each other in every direction. By far the greater number have had no development, and are simply claims that have been staked off and named.

These claims are the result of the recent developments in what are known as the Bonanza mines, whose works are farther east than those of the older mines, and of a better understanding as to the dip of the vein, which in earlier

times was thought to have a westerly direction.

There are but two in this vicinity that have made any progress worthy of record. The first to be mentioned and the first that was located is the

Wells-Fargo.

This claim was staked off in January, 1873, on what is believed to be a continuation of the rich ore bodies now yielding their marvelous millions and in ground which had the orthodox surface color. The original claim was 200 feet wide and 1,500 feet long, with a northeast and southwest course, 2,700 feet east of the Utah and 3,000 feet north of the north line of the Ophir. A company was incorporated under the Nevada State law with a capital of \$3,600,000, divided into 36,000 \$100 shares, under the title of Wells-Fargo gold and silver mining company. Before much work was done an arrangement was made to consolidate this with an adjacent and parallel claim, owned by the St. Louis gold and silver mining company. This was also an incorporation under the Nevada law, with same amount of capital and same number of shares. In the consolidation it was desired to give to the Wells-Fargo stockholders twice as many shares as to the St. Louis company, therefore the number of shares was increased to 108,000, giving 72,000 shares to the stockholders of one company and 36,000 to the other, and increasing the capital stock to \$10,800,000. The new company thus formed has an area of 27 acres, and was incorporated in San Francisco in 1874, under the name of Wells-Fargo mining company. Since that time the company has been steadily prospecting, with probably more intention of economy than speed, which it seems are not usually compatible in this kind of work.

The Result of their Operations

To date is a shaft down 600 feet and a level at 500 feet, with an east and west drift. Twenty feet from the shaft in the last drift an orebody was struck of blue clay and quartz, and the drift still keeps in this low grade ore. The work of sinking shaft and running drifts continues without interruption. The hoisting works are placed near the center of the claim, and are conveniently situated for dumping and for whatever extensions future developments may require. On the grounds are carpenter and blacksmith shops and boarding houses, the whole making a fair showing for the amount of money expended, there having been but three assessments altogether, aggregating 55 cents to the share. The office in San Francisco of this company is at room 13, Sale Deposit building, and the present officers are D. L. McDonald, President; O. H. Bogart, Secretary, and O. R. Johnson, Superintendent. The latter gives his personal attention to the mine, and to his foresight is due the laying out into streets and lots of the projected town called North Virginia. Firmly believing in the future of this locality, and foreseeing the confusion and antagonism which arises from each man's putting a house wherever it suits his convenience, he wisely put in a claim for the surface ground, not to interfere with any mineral right, and had it so laid out as to make a well arranged town. About thirty houses have been built here, forming the nucleus of the future city.

The only other mining claim in this group which has had any development worthy of notice is the

Troy Consolidated,

and it is to be regretted that at this time no information can be had of its present condition, from the fact that work has been suspended, not, it is believed, from the absence of favorable indications, but from some financial difficulties. Several original claims, the True Blue, Bank of California and Sierra Nevada No. 2, and maybe one other, constitute the property of this company, making a large area. There are good and substantial buildings on the grounds, and the hoisting works are supplied with a large engine and all necessary appliances. The present depth of shaft and what other work has been done in the mine cannot be ascertained now, but a depth of 250 feet had been reached nearly a year ago, and some of the rock found suggested the belief that the north extension of the rich ledge had been found.

As soon as work is resumed more definite and detailed information will be obtained about this mine; meantime, in my next letter will endeavor to tell you something of other mines at the north end.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANKS.]

(Continued from last Week.)

Jet and Cannel Coal.

Although not strictly coming under the denomination of gems, yet as they are frequently made use of as ornaments, they naturally take their place among minerals used for ornamental purposes.

Mineral coal is a mixture of several hydrocarbons, and in its usual form is too common to require description. The two varieties

for ornamental purposes. It occurs in masses, has conchoidal fracture, is opaque, has a shining luster and is of a "jet" or pitch black color. It yields to the knife, having a hardness equal to 1.25, specific gravity equals 1.29–1.35, burns with a greenish flame, and emits in doing so a strong bituminous smell, becomes electric when rubbed and is very brittle.

Jet is sometimes called "pitch coal," or "black amber." It is found in England, Prussia, Italy, Spain, France and elsewhere.

It is much esteemed for mourning ornaments; it can be highly polished and worked into many ornamental forms. Indeed, it is astonishing to observe the results of the ingenuity of the jet workers in inventing new varieties of ornaments to tempt the purchaser.

TABLE OF CELEBRATED DIAMONDS.

NO.	NAME.	WHERE FOUND.	QUALITY.	COLOR.	WEIGHT, UNCT.	WEIGHT, CUT.	VALUE.	BY WHOM OWNED.	HOW CUT.
1	Braganza.	1741.	Brazil.	Supposed to be a white Sapphire or Topaz.	White.	1880 Carats.	Estimated \$278,400,000	King of Portugal.	Uncut.
2	Great Mogul.	1552.	Golconda, India.	Small flaws; otherwise, 1st water.	White; Limpid.	780½ Carats.	299.56 Carats.	Grand Mogul.	Rose.

21	Florentine.				Light Yellow.	139½ Carats.		Emperor of Austria.	Rather thick Rose.
22	Pachaoi Egypt.			Good quality.		40 Carats.		Ibrahim Pasha.	Octagonal; Brilliant.

named above are not so common as others, and to them only I call attention.

Cannel coal is a variety of bituminous coal found sparingly in various parts of the world. Like other coal, and like the diamond, it is of vegetable origin, and has undergone many changes during process of formation. It is compact, has little luster, breaks with a conchoidal fracture and shining smooth surface. It affords on distillation a large proportion of hydro-carbon oil. The celebrated "Parrot cannel coal" found near Edinburgh, Scotland, is so called because when heated it decrepitates with a sound thought to resemble the voice of a parrot.

Another cannel coal, also from Scotland, is called "Torbernite" or Boghead coal. Cannel coal can be turned in a lathe and fashioned into ornaments of considerable beauty.

Jet is a variety of cannel coal much valued

for ornamental purposes. It occurs in masses, has conchoidal fracture, is opaque, has a shining luster and is of a "jet" or pitch black color.

The "True Whitby jet," so extensively advertised, comes from Whitby, in Yorkshire, England. It is found in fragments of medium size, in clay. Glass, vulcanite and enamel are sometimes substituted for it.

Jet was well known to the ancients under the name of Gagates, so called from its having been found at Gages, in Syria.

Pliny, as usual, ascribes medicinal and other virtues to it, such as the following, which I quote:

"The fumes of it when burned keep serpents at a distance, and dispel hysterical affections;" "A decoction in wine cures toothache," etc.

Large quantities of manufactured jet find a ready market in Spain and Turkey.

The sum of £20,000 is stated to be the annual value of the Whitby manufacture.

General News Items.

The iron door of the Bergen tunnel magazine, at Jersey City, was found two miles distant after the explosion.

The New York Herald prints a letter from Midland, Georgian bay, Canada, certifying that Boss Tweed and two companions spent the Winter on Muskota river, 30 miles from Midland and 100 miles from Toronto.

In the case of the monte sharp against the Union Pacific railroad, for damages for having been put off the train, in the Court at Omaha, the jury gave a verdict of \$1.74. The judge said the company had a right to eject gamblers.

The State militia are in requisition in Massillon, Ohio, to prevent the outbreak of the coal mining strikers.

PESACH N. RUBENSTEIN, the condemned murderer of the Jewess, Sarah Alexander, died at Raymond street jail. Cause, general debility.

A WASHINGTON dispatch, speaking of the Belknap case, says: A decision will not, it is thought, be reached for two weeks to come; but the impression prevails to-night that the Senate will decide in favor of jurisdiction.

NEARLY \$200,000 worth of silver was paid out Monday at the New York Sub-Treasury in redemption of currency. Owing to the heavy demand further silver payments have been suspended to await advices from Washington.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa County, Cal.
 Notice is hereby given, that at a meeting of the Board of Directors, held on the second day of May, 1876, an assessment (No. 3) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, No. 309 Montgomery street, room 33, Nevada Block, San Francisco, Cal., or to the Assistant Secretary, at the office, No. 3 Nassau street, New York.

Any stock upon which this assessment shall remain unpaid on the third day of June, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the 30th day of June, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, L. E. N. DEXTER, Secretary.

Office, Room 33 Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Amador Canal and Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Jackson County, Cal.
 Notice is hereby given, that at a meeting of the Board of Directors, held on the ninth day of May, A. D., 1876, an assessment, No. 1, of three dollars (\$3.00) per share was levied upon the capital stock of the corporation, payable immediately, in U. S. gold coin, to the Secretary, at the office of the company, room No. 2, 418 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 15th day of June, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the 15th day of July, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, J. W. OLARK, Secretary.

Office, Room No. 2, 418 California street, San Francisco, Cal.

Schofield's
SULPHURET CONCENTRATOR.THE BEST MACHINE IN USE FOR
SAVING SULPHURETS.No Power Required to Run it, and only a Small Stream of
Water under a Light Pressure.ECONOMICAL,
EFFECTIVE,
DURABLE,
AND SURE IN OPERATION.The especial attention of parties erecting new mills is called to this
Valuable Improvement.

WE GUARANTEE THAT THIS MACHINE WILL SAVE NINETY PER CENT. OF ALL THE SULPHURETS
IN THE ROCK AT A MERELY NOMINAL EXPENSE. IT HAS NOW STOOD THE SEVERE
PRACTICAL TESTS OF OVER A YEAR'S WORK AT DIFFERENT MILLS
ON THIS COAST, AND HAS BEEN EMINENTLY
SUCCESSFUL IN EVERY CASE.

The following letters, from practical men who have used this machine, will show to
those interested what it has accomplished:

BANDERETA MINE,

Mariposa County, Feb. 7th, 1876.

CHAS. SCHOFIELD, Esq.—Dear Sir: We have been using your Concentrator at our mill about six months, and find that it saves over 90 per cent. of the sulphurets contained in the ore, and all of the amalgam and quicksilver which escapes from the battery. The machine is simple in construction, perfect in operation, and requiring no power to run it, is very economical. I can confidently recommend it to all mill men as the best and cheapest Ore Concentrator now in use.
 Yours respectfully,
 LEVI NOEYS, Superintendent.

NONPAREIL GOLD MINING CO.'S WORKS,

Deer Flat, Tuolumne County, Cal., April 12th, 1876.

MR. CHARLES SCHOFIELD—Dear Sir: It is four months since the Sulphuret Concentrator you furnished our company's mill with was first put in operation, and during the past three months has been nearly in constant use. The men attending the Concentrator having acquired by practice a thorough knowledge of its workings, there is nothing more to be desired; it is perfect. A number of mill men have examined the Concentrator and its workings, and pronounce it the most simple in its construction, perfect in its work, and cheaply run of any they had seen. If you think by showing this it will assist you in disposing of your Sulphuret Concentrators, you are at liberty so to do, as it will afford me much pleasure in having contributed my little mite towards rewarding true merit. Hoping you will meet with complete success,
 I remain yours truly,
 JOS. J. DUPRAT, Superintendent.

CON. ALABAMA M. CO.,

Tuolumne County, May 1st, 1876.

C. SCHOFIELD, Esq.—Dear Sir: The Concentrating Machine recently purchased of you is now in active operation, and we are highly pleased with it. It saves over 90 per cent. of our sulphurets, and is run with very little expense. We could not afford to be without it, and can safely recommend it to all mill men as the best and most economical machine in use.
 M. S. McCONNELL, Superintendent.

WASHINGTON MINE,

Mariposa County, Cal.

CHAS. SCHOFIELD, Esq.—Dear Sir: Having had one of your Double Rigged Concentrators in use now at this Mill for over a year, I take this opportunity of informing you that it is far superior to the old English Biddle we have been using for the last four years, not only in a saving of labor, but having a less waste of sulphurets in washing.

We have the machine connected with the tail sluice, and receives the sand and water direct from the batteries, without any handling, and it does the concentration for the 20 stamps easy, with a loss of less than 10 per cent.

Two Chinamen do all the work required—one night and the other day—working 12 hours each, and get out about a ton each day, thus concentrating 30 tons into one, at a cost of less than four dollars. As the cheapest, most economical and best working Concentrator I know of I can recommend it to others without any hesitation.

Yours truly,

GEO. E. WEBBER, Jr.,

Superintendent Washington Mining Company.

MR. SCHOFIELD—Dear Sir: Having carefully examined your Concentrator, which I have seen in successful operation at the Francis Company's Mill and also at the Benton Mills, on the Mariposa Estate, I have no hesitation in saying that it is the most valuable Concentrator I have met with during my long experience as amalgamator in this country. Its manner of catching quicksilver and amalgam is thorough and complete, and it saves the sulphurets clean and with a loss of less than ten per cent.

Yours respectfully,

L. BURDOW.

MR. C. SCHOFIELD—Sir: I have worked one of your Sulphuret Machines at the Benton Mills about 30 days, and am satisfied it is the best machine for saving amalgam and sulphurets ever used on the Mariposa Estate.

L. GILMAN.

The following testimonial is from the well known mining expert, PROF. J. E. CLAYTON:

CHAS. SCHOFIELD, Esq.—Dear Sir: Having followed the business of mining engineering for upwards of 30 years, and having had in this connection much to do with regulating machinery for saving gold and concentrating sulphurets, and having in nearly every mining camp on the Pacific Coast examined the various kinds of Ore Concentrators in use, I will say that I have nowhere seen anything half as cheap and simple in its construction, scientific in principle or effective in operation as your machine.

J. E. CLAYTON.

Machines can be Furnished at Short Notice. In all Cases we Furnish the
Concentrator Complete, Set it Up, and Instruct the Buyers as to
the Proper Way of Managing It.

Steam Pumps and Fuel.

A correspondent of the Gold Hill News says: The tests made by the Mechanics' Institute of San Francisco are most valuable to miners who are compelled to use the ordinary steam pump for raising water, as it proves that however convenient they are for temporary purposes, they never ought to be used as a permanent engine to drain mines. Hitherto it has been well known that they were expensive, but the cause was allowed to be entirely in the length of steam pipe and the condensation therefrom. But these tests have shown this to be erroneous, and that the fault lies in the manner of working the steam non-expensively, and in the arrangement of the steam valves, and at high motions in the pump valves.

Taking the report of the committee on the best pump, we find that the amount of steam displaced by the piston, or the effective steam, was only 42 per cent. of the total amount of steam passed through the cylinder, and the "duty" of the pump was 17 pounds of coal per horse power per hour.

When this is compared with the duty of first-class compound engines, whose duty has been as low as one and one-half pounds of coal per horse power per hour, and that a good fair figure for compound pumping engines is two and one-half pounds, it will be seen that these pumps ought never to be used as a permanent pump. As these tests were made with a short steam pipe, it is evident that the great waste is not due to the long pipe in mines, and experiments have demonstrated that the condensation which takes place in pipes of a thousand feet in length does not exceed a half pound of coal per horse power per hour when connected with first-class compound engines, and that in the ordinary steam pump it is the cause of but a small percentage of the loss.

In many of the mines these common steam pumps are used with compressed air instead of steam, and what the loss is on them, even where no condensation can occur, ought to be demonstrated by careful experiment; but approximate results show that it must be very great. Unfortunately no record is kept, and generally the different engines are all connected with the one set of boilers, and no separate account can be made. Who amongst our mining engineers will, for the information of the public, give the true data on the above subject?

ONE estimation is that the Big Horn district, as well as the Black hills, will be deserted in a month. Another estimate is that over 5,000 miners will be in the Big Horn district, Montana, by the middle of May. Readers can take their choice.

HUNTINGTON, HOPKINS & CO.,

Sole Agents for the Pacific Coast,

Junction of Bush & Market Sts., S. F.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

Giant Powder.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING

THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS

ON THE LEGS OF TRIPOD, ARE ALL IMPROVED

AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never fails of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

Automatic Boiler Feeder and Regulator.

We illustrate on this page Cook's patent automatic boiler feeder and regulator, which has attained a high reputation in the Eastern States, and is now for the first time introduced on this coast. Its economy of operation, together with the protection it affords, renders it an object of great interest to all users of steam boilers.

Figure 1 represents the feeder in operation; Figure 2 represents it with the man-head out, showing its construction and parts as follows: The body of the feeder is a boiler-iron cylinder, 20 to 30 inches in diameter, and from 30 to 60 inches long, as may be desired, having a cast iron head with a man-hole in the front head. B is a valve or three-way cock, to let on and exhaust the steam from the cylinder. A, F is a float shaft and lever to turn the wheel, C. The float, J, is a hollow cast iron cylinder (shown in Fig. 2), and attached to the float shaft by arms at each end. L is a man-head with counterbalanced wheel attached. The operation is as follows: As shown in Fig. 1, the feeder is empty and the steam exhausted from the shell, A. The water will flow from the supply tank through the pipe, G, by its own gravity, and fill the feeder; as it fills, the float, J, rises, and the lever, F, turns the wheel, C, and this lets the steam pass through valve, B, on top of the water. The pressure between boiler and feeder is now equalized, and the water will flow through the pipe, O, to the boiler until the feeder is empty, or the water line in the boiler raised up to the end of the pipe at H, when the water will close the end of the steam-pipe, H, and stop any further supply until needed.

When the feeder is empty the float, J, has descended to the bottom of the feeder, and in so doing has cut off steam by means of a valve, B, and opens the steam exhaust port. It will again fill, and will continue thus operating as fast as the boiler receives water, keeping the water line at one limit all the time.

When it is necessary to take water from below the boiler, the feeder forces it up, using an iron tank for the purpose and one more pipe than shown in the engraving. It is impossible for the feeder to fail to put the water into the boiler if it moves at all. It is simpler than any pump and more durable, as it will discharge from 40 to 200 gallons at one movement, where a pump would require hundreds of strokes to do the same work. Moreover it is automatic and requires no judgment as to speed, like a pump. It works equally well under 200 pounds pressure, or using hot or cold water. It has great economy of fuel to recommend it, as it supplies water in exact proportion to that evaporated, and maintains an exact water line at all times, saving a large proportion of fuel.

The machine does not require to be started or

stopped, as in all its functions it is entirely automatic. Cook's automatic boiler feeders were awarded the highest premium over all machines exhibited as boiler feeders at the Cincinnati exposition and St. Louis fair, in 1875. Goddard & Co., Pacific iron works, in this city, agents for the Pacific coast, exhibit numerous testimonials as to the efficiency, economy and safety of this invention, and expect to introduce it extensively here. This feeder is also made with a heater and regulator combined. The heater is an excellent one, putting the water into the boiler at near the boiling point, and the feeder maintaining a uniform water line.

Fig. 1.

COOK'S PATENT AUTOMATIC BOILER FEEDER AND REGULATOR.

These inventions insure safety in preventing boiler explosions and in economy of fuel. One of the feeders may be seen in operation at the Pacific iron works, First and Fremont streets.

The *Amador Ledger* says: "Some of the magnates of the Central Pacific railroad made a visit to Ione during the week, on business pertaining to the early completion of the branch road to Ione. The citizens have fixed upon the 4th of July as the time for opening the road, and intend to signalize the event by the grandest celebration ever had in the valley."

COPPER IN WASHINGTON TERRITORY.—The copper mine recently discovered on Gumes Island, near San Juan, Washington Territory, promises to prove valuable, although very little work has been done as yet. At twenty feet from the surface ore which assays 25 per cent. of copper has been struck.

In the trial of the Mary Ann company vs. The Pacific Consolidated mining company, for 600 feet of mineral ground in Cherry Creek district, the jury disagreed and were discharged, after a deliberation of twenty hours.

The Centennial at Philadelphia.

[Editorial Correspondence.]

PHILADELPHIA, May 9th, 1876.—Your correspondent arrived here yesterday morning and, though much fatigued and covered with the dust of 3,000 miles of travel, made a hasty toilet and proceeded at once to headquarters on Walnut street, to secure the permit necessary to enter the grounds—a permit to enter the buildings being peremptorily refused to all except those actually engaged in preparing their exhibits. Having reached the grounds, however, and passed the outer sentinel, your correspondent resorted to one of the many ways so well known to newspaper reporters, and soon found himself inside of the great exhibition building, and free to move as inclination dictated.

Bustle of Preparation.

Our first thought on looking upon the almost endless confusion of full and empty boxes, the huge piles of dirt and refuse and the imperfect display of exhibits generally, was that it would be utterly impossible to bring order out of such chaos in the brief time of a day and a half that remained for such preparation. But on a second thought, after viewing the great army of

however, that these were the last trains that would be allowed to enter the enclosure, and was furthermore assured that all the confusion I saw around would be transferred into admirable order by to-morrow's morn.

A Terminal Agency

Is now actively engaged in the general superintendence of these final preparations, compelling exhibitors to hurry up their work, remove their rubbish and get ready for the grand opening to-morrow. Some idea may be formed of what has been done from the fact that about 3,000 car loads of goods have been received—100 a day for the last three months. This is all in addition to the local exhibitors, who are numerous, and who have taken their goods to the buildings in drays and express wagons. No less than 847 wagon loads were so received in one day—Saturday last—and this morning it is stated that fully as many loads entered the grounds yesterday. A comparison of these means of transport and the foregoing data will enable a San Franciscan to institute some comparison between what is promised by a world's exhibition in Philadelphia and a Pacific coast exhibition in the Golden City. This morning all the gates were closed to cars and wagons, and only small packages and lots will hereafter be received, under special permits.

Fig. II.

The Centennial Commission met at the judges' pavilion, on the grounds, yesterday afternoon, to attend to some of its final preparatory duties. At this meeting Judge Creigh, of San Francisco, and the Commissioner for California, was called to the chair. The Committee met again at 10 o'clock this morning, for final action.

Preparations for the Opening.

All Philadelphia seems to be preparing for the grand event of to-morrow. The mayor is out with a proclamation this morning requesting the closing of places of business on the occasion, and a general illumination in the evening. It is said that the decorations and show of bunting, both public and private, will be on a grand scale. The Centennial bell will be rung for half an hour at sunrise, noon and sunset. The church bells will

also be rung at the same times. A grand platform is in progress of erection against the wall of memorial building, and a corresponding one on the opposite side of the space, against the wall of the main exhibition building. Seats are being put up sufficient for the accommodation of at least 5,000 persons—the most or all of whom are especially invited to the platform. A wise determination seems to have been arrived at to make the opening ceremonies simple and brief. Only "words few and fitting" will be spoken. But readers of the Press will have been already fully informed of these opening exercises by telegraphic report before my writing can reach them by mail.

The Buildings, Grounds, Etc.

Of course, during the limited time allowed me for examination yesterday, I could learn but little of the progress which has been made in putting up and fitting up the various annexes of the different States and nations. I shall examine all and them at my earliest leisure.

The Bank of Nevada county, which suspended a month ago, will re-open, it is stated, on June 16th.

CORRESPONDENCE.

Botanical Excursions.

[By J. G. LEMMON.]

No. 2. The Northern Valleys and Lassen's Peak. (Continued.) Part III. Indian Valley and its People.

Exploring the broad breast of Prince Sierra thus far, reveling among his elaborate decorations, we have found much to admire, much to excite curiosity, and much to show his high standing in society. We have discovered, if hedges are a sure indication, that he inherits the crescent of the Oriental caliphs, has joined the Odd Fellows, become a Royal Arch Mason, and been honored with the microcosm—the insignia of a master of natural history and philosophy. We shall find further that he has been knighted with the beautiful Maltese cross, wears the glittering shield of a union defender, has mounted the stars of a commander-in-chief, and sways the scepter of a king.

Indian Valley.

Entering Indian valley from Butterfly valley by way of the Quincy toll road, we emerge first upon the south arm of the Maltese cross, and a most entrancing scene lies before us. Nestled down, in and out among the warm beses of the mountains, lies the jewel, its center embossed by several sugar-loaf islands, its arms extended and passing out of sight among the crowding, brown, oak-bordered mountains. Fences and farmhouses everywhere checkmark and punctuate the plain, but, as in Sierra valley, its villages are hid away in the far corners. Several days of delightful travel will reveal wonderfully beautiful nooks and dells sequestered along the border, while its arms are deltas of alluvial riches to the practical eye, and alcoves of picturesque scenery to the naturalist.

Yes, Indian valley has fields, gardens and meadows—none richer in the State; it has roads, bridges, fences and barns; it has school-houses, churches and society halls; it has quartz and flouring mills, lumber and furniture factories; it has mining camps and thriving villages; it has shops and stores—aye, and it has gambling dens and whiskey holes, too; but I see not these now, I recall not these elements of prosperity, I only see its comfortable homes and think of the warm-hearted people residing in them.

A Social People.

I think of the long years of frequent visits to that sweet vale, and the kind attentions ever tendered me by its citizens. Every house was my home, every person my friend. Never was a people better characterized for hospitality.

Then there are active minds there, those that hunger and thirst for knowledge. There are hearts that throb responsive to throbbing hearts, souls that are knit unto souls. I cannot discriminate where all are so kind, but some insist upon their friendship in a way that is irresistible. They seize you by the hand and drag you into the house, while confederates steal your horses, hide the harness and lock your wagon in the barn; then all gather round you with speaking faces. They look you in the eye and question you closely. Eyes dance and voices ring with joy if you are merry, they fill with tears and tremble with sorrow if you have woes to relate.

From this description the reader will naturally infer that the people of Indian valley are fond of social visits, dances and open-air festivals. You can scarcely enter the valley any day in summer without seeing a company of citizens, old and young, gathered in a grove enjoying a picnic. A Grange recently organized there also furnishes entertainment of a high character. In the winter not a day of any note in the calendar is allowed to pass uncelebrated by a dance or festival—beside, there is a regular social club that gives entertainments at frequent stated intervals.

The Picnic.

It was into this community that Larsen and I entered one golden day last summer. It happened to be the 24th of June, St. John's day. I assured my comrade that the day would be celebrated, of course, and 12 miles away, in Genesee valley, we heard of a Mesonic picnic at Taylorsville and drove straight for it. There were half the residents of the valley assembled under some noble pines—tables, seats, speaker's stand, orchestra, canopy, and a merry-go-round for the children propelled by a horse—nothing lacking for a good old-fashioned picnic.

I had been among these people years before, teaching misal geography, riding the circuit of their districts weekly for a winter, and had often visited them in summer botanizing, but their early enthusiastic friendship was scarce abated. What a hand-shaking and greeting! Solicitations poured in on all sides to go home with this family and that. Dr. Hunt and his wife, being large persons, and friendly in proportion, proved well nigh successful, but Mr. Ames, about a match for the doctor, and his wife, being the botanist of the valley, they overcame all, and promising the doctor and his family an early call, as they termed it, of a day and two nights, we drove straight for the pleasant home of Mr. Ames, away up in the north arm among the low, thick-leaved oaks.

The Botanical Feast.

A royal feast followed! All Mrs. Ames' col-

lection of the season was displayed, also packages received from foreign parts in exchange for Sierra plants. To this display was added her extensive botanical correspondence—letters of inquiry; of congratulation from Drs. Gray, Canby and Thurber; from Profs. Watson, Woolson and Congdon, and from many other scientists of less note—all drawn to her by the exceeding merit of her labors, the readiness of her assistance and the beauty of her letters. The proceedings of the American academy of sciences at the East make such frequent mention of this California botanist and collector, that perhaps the *RURAL* readers would like a pen-picture.

Mrs. M. E. P. Ames, the Botanist.

Mary E. Pulsifer is the eldest of two sisters, only children of John W. and Silena Pulsifer. She was born in the city of Lowell, Massachusetts, about 35 years ago. (I am not positive as to dates and am writing this sketch without the slightest intention or expectation of doing so until this moment.)

Early in the great California exodus, I think in '49, Mr. Pulsifer came to this country, hastened into the mountains and soon penetrated this secluded valley in search of gold. He prospected carefully the quartz ledges in the enclosing mountains and discovered a rich one, where afterward sprung up the village of Crescent. He developed the mine, sold out, acquired several thousands, and returned East for his family, then, I believe, in Iowa.

Taking them again to Lowell and putting the daughters in school, he resided there some years, then with his family emigrated to California, to make it their home.

Locating in the semi-tropical Santa Clara valley, the youngest daughter, Martha, found food for her intellectual and literary tastes, while Mary, intensely fond of flowers from infancy, was in Paradise. The careful parents placed their promising daughters in the Santa Clara college to finish their education, and opened their house for the reception of the best society of the valley. Here Mr. Pulsifer gave loose rein to those social, intellectual and philosophical desires that through life had struggled for exercise, and he became noted for intelligence, research, social magnetism and generous assistance.

The old mining fever working still in his veins, impelled him to remove for a few years to Shaw's flat, in the southern mines. Here the diligent young botanist added to her specimens the peculiar flora of Table mountain. Here was a stepping stone to the high Sierra, a foretaste of its alpine flora. The next remove was to the early home of the bold prospector, over the Sierra, the flower-gemmed Indian valley.

Purchasing a ranch in the north arm, and surrounding his family with home comforts, Mr. Pulsifer continued those mental recreations and philosophical researches which drew around him a large circle of friends. Among them appeared Mr. C. C. Ames, a clever, generous, well-to-do gentleman, who had often accompanied the botanist on her explorations of Table mountain, and now continued his attentions. He fully appreciated her worth and talents, and she his great soul and devotion, so they were married in September 1871. Carefully providing his wife with presses, papers, receptacles and stamps, and always ready to carry her about the country with his fast trotters, wedded into the bogs or climb a rock for her flowers, he proves the best husband a lady engrossed in the expensive, non-paying pursuit of botany could have. Her parents also appreciated and assisted her, no child of the forest wild being sharper-eyed in the detection of flowers than her mother.

The father, a tall, noble gentleman of the old school, looked with proud satisfaction upon his fond daughters, and deeply enjoyed the success of each—Martha in the realm of letters as a newspaper correspondent, Mary in the floral kingdom winning honors and fame imperishable.

But the successful farmer must give close attention to dull details and delight in it. Mr. Pulsifer was a socialist, a philosopher. Having quit the digging of gold he could make it no other way. The farm passed into the hands of others, and father, mother and Martha returned to San Jose to renew the friendships of early times. Here the family met with the loss of its noble, divinely endowed head. Here died, September, 1874, Mr. Pulsifer, aged about 63, in the midst of warm friends, and supported by his wife and Martha, but far away from the loved and loving Mary.

Mary almost idolized her father, and the arrow of death nearly transfixed two where one was menaced. Mr. Ames, who had built up a home adjoining the old ranch, immediately sent for the stricken mother and Martha and has provided them a home with him for life, if they choose.

Mrs. Ames, rallying by the assistance of her mother, now doubly endeared, found in the continuance of her botanical surcease of sorrow, remembering the while how, in life, her proud father shared and heightened her triumphs. She made long excursions up, down and over the Sierra, barely escaping the total loss of sight in her zeal—happily now recovered. She reduced her large collection in order to facilitate their study.

Then, when questioning letters crowded every mail, she could readily pen a neat reply right to the point; so fully, so correctly, so cheerfully written, that every questioner was at once tempted to submit twice as many more. Thus Mrs. Ames has labored, thus she has been enabled to be of so much use to the editors of the "California Flora."

In long, fatherly letters from Dr. Gray, he gives her warm encomiums for zeal, knowledge and efficiency; and in his "Botanical Contributions," read before the American Academy of Arts and Sciences, he speaks of Mrs. M. E. P. Ames as one of the collectors on whom he chiefly relies for the flora of Northeastern California.

Among her collections are scores of plants rarely found before, and a dozen new ones, two of which (and perhaps more this winter) have been named in her honor, *Astragalus Pulsifera* and *Mimulus Pulsifera*.

When the first of these honors was announced to her, Mrs. Ames replied: "My spirit is dumb with joy! Oh, if my dear father had lived to share with me the joy of this hour, my happiness would be complete! How can I express the depths immense of endless gratitude I owe the good Dr. Gray!"

This extract, characteristic of Mrs. Ames' letters, is enough in conclusion to convey to the reader an idea of the mind, the heart, the spirit of this gifted child of nature, who reflects so much credit upon the region of the high Sierra where she lives and upon the State at large.

Calaveras County Quartz Mines.

It is entirely within the bounds of truth to say that the quartz mining interest of this section of the country never wore so favorable an aspect as it has this spring. New ledges are being discovered, abandoned mines reopened and mills being erected in all the districts. Capitalists are investing freely in mining property in several localities, and the work of development is being pushed with untold energy in every direction. There is no question but that this county offers better inducements to those wishing to engage in quartz mining enterprises than any other section of the State, and it is an encouraging fact that our advantages in that respect are beginning to be appreciated and utilized. Two of the more noteworthy reasons why Calaveras is the most inviting field for quartz operations, are the great number of ledges and the fact that the majority of them are as yet unprospected or in a state of partial development. The quartz belt in this county is fully fifteen miles in width, on an average, and the entire area is traversed by gold bearing lodes. There is yet abundant opportunity for obtaining claims by location, or promising veins, in almost any desired state of development, can be purchased at any reasonable figures. It is a knowledge of these advantages that is turning the attention of miners and capitalists towards this county, as offering the most favorable field for profitable labor and investment, and the effect is easily observable in the inception of new enterprises and the increased vigor with which operations are being pressed. With the influx of capital, largely increased milling facilities are being provided in all the districts, and the erection of machinery necessary for the proper working of the mines is promoting development to a degree hitherto unknown. That fully one-third more quartz will be milled in this county the present season than during any previous one, is not an extravagant assertion, and in view of the introduction of improved methods of working ores we are safe in saying that the gross yield will be engendered in still greater ratio.

At the Gwin, the principal mine in the county, the outlook was never before so wholly favorable. The 1100-foot level and its stopes are furnishing an abundance of first grade ore, and there are evidences that the pay chute will prove more extensive at the present depth than at any point nearer the surface. All the batteries are kept constantly employed, the product of the mine ranging from \$4,000 to \$5,000 per week. By good management the working expenses of the mine have been greatly diminished, without lessening the ore product. The work of sinking the shaft an additional hundred feet, for the purpose of opening a level at the depth of 1,200 feet, has been commenced. In the West Point district unusual activity is also noticeable. The principal mines—the Champion, Josephine, Mina Rice and others—are being worked steadily and with good results. In the Glencoe district also, operations are being pressed vigorously. The San Bruno, Gresham and other leading mines are in the hands of men of means, and with the aid of recently erected machinery are being systematically worked. Powerful hoisting works are shortly to be erected on the Glencoe Consolidated and other mines, and the prospects of the district are altogether cheering. In the Jesus Maria district sales of valuable mining properties have lately been made, and preparations for active work are progressing. Intelligence relative to operations in Sheep Ranch district is also flattering, the principal mines continuing to yield well with good prospects of several new enterprises being added to the list of paying claims. In fact, taken as a whole, the quartz mining interests of the county were never in so flourishing a condition, and beyond a doubt the present season will be the most prosperous one Calaveras has ever known.—*Calaveras Chronicle*.

In the Julia mine on the Comstock the face of the main drift on the 1800-ft level is developing a new feature in the shape of almost boiling hot water. This water is hot enough to scald, and is undoubtedly the result of the decomposition of minerals in the ledge at some point not very far away.

Alpine County Mining Interests.

Since the first settlement of this county, says the *Alpine Chronicle*, there never has been such healthy activity in mining interests as we are now daily witnessing in the several mining districts of Alpine. After years of neglect by the capitalists of our own State, for which, in a great measure, the early locators are responsible—they fearing that the Sacramentans and San Franciscans would "cinch" them too strongly, a reaction has occurred at the Bay city and the mines of Alpine county are now attracting the attention they should have received years ago. This better state of feeling toward our mines is the result of a radical change in our system of mining—the inauguration of shaft sinking, instead of the tunneling process, so long the curse of this county. Manager Chalmers, of the Exchequer mine—owned by a London company—was the first to change the programme that had become second nature to our people, and what is the result?—as soon as the iron horse and the screw propeller can do their work the London owners will have placed before them "silver bricks"—the best evidence that they can ask for as to the value of their Alpine possessions. The fine developments made in the Exchequer shaft have spurred on others, and the future of Alpine is no longer in a fog—it is as clear as the noon-day sun, that her treasure crop will not be second to the great Comstock itself! As an evidence of the increased interest in our mines we may state that a year ago the Exchequer, at Silver Mountain, was the only claim being worked, but now, with the Exchequer, we have the Advance, at Monitor, with a large three compartment shaft down 200 feet, and work going on, the Flint, also at Monitor, with a shaft down some 50 feet; the Illinois-California, in the Raymond district, running a tunnel now in over 1,200 feet with good prospects. In addition to these we learn that heavy machinery will be put on the Silver Cloud as soon as the roads will permit; and a new set of hoisting works with powerful machinery will be immediately put on the Advance, and also on the Flint. It is said that the Lady Franklin, I. X. L., and the Adolphus and Pine Tree, at Silver Mountain, will shortly be started up, and work will soon be inaugurated on the Marion, at Monitor, lately purchased by San Francisco parties. Negotiations are pending for a change in the ownership of two prominent mines here. Now is the golden opportunity for capitalists wishing to invest in mines to suit themselves on good terms, for in another year the value of mining property here will naturally increase as kindred properties are developed. What with the work already laid out and in contemplation, and that which will naturally follow in the wake of such enterprises, the coming summer will be the most prosperous season Alpine will have seen.

A New Water Jacket.

Last week we spoke of the new water jacket of the Defiance mining company, and in doing so inadvertently committed an error as to the inventor. Our information was obtained second-hand in regard thereto, but since another gentleman is entitled to honorable mention in connection therewith, we not only freely make the correction, but will endeavor to explain more fully the important points of the new jacket which makes it so preferable to the old style. The new water jacket is spoken of in the caveat filed for patent as the "Shepard & Rawlings' improved water jacket," and its main points consist in a combination of a steam and water chamber, which, by its peculiar construction, is connected with and joined to the top of the water jacket, the top being expanded all around six inches larger than the main jacket, and extending one foot above the same, the one foot extension above being lined with fire brick to prevent burning and an undue amount of heat of the water contained in the expanded top. What is claimed for this style of jacket is that it does not consume as much water, produces more steam, and consequently is a saving in the boiler generating steam to run the works; is much safer, not being liable to become dry and burn out, nor to any explosion. There are many other good points claimed for this water jacket, among which is a peculiar opening in front to facilitate the cutting out of a "bank" or cleaning the furnace, which can be done in much less time and at much less expense than in those of the old style. The steam drum, or expanded top, is an invention of Mr. J. H. Rawlings, who is a practical inventor, and is now employed as engineer of the Defiance furnace. The front opening for the easy cleaning of the furnace or cutting out of a "bank" is the invention of L. F. Shepard, who has been a practical furnace man at Cerro Gordo and other places for the past five years, and is now employed at the Defiance furnace as superintendent. As this new jacket is now on its first trial we shall watch with peculiar interest its operation, and of its success or failure we shall have more to say hereafter.—*Osos Mining News*.

In the Best & Belcher mine nothing is doing at present, the north drift on the 1700-ft level connecting with the Gould & Curry having been repaired, and the temperature being too great to yet attempt to cross cut. The Best & Belcher is equally interested in the new pumping machinery now being erected by the Gould & Curry, and must wait until the improvements on the shaft and the erection of the machinery is completed, before the development of the lower levels can proceed.

MECHANICAL PROGRESS.

How a Hatchet is Made.

As an illustration of the ever advancing progress in machinery, we quote from the *British Trade Journal* the way hatchets are made in one of the large Sheffield establishments: The long bar of iron out of which they are made is cut into lengths, called molds, by powerful shears. One of these molds is heated to bright redness, and a piece of steel welded on to the central part, to form the poll of the hatchet. One-half the length of the mold on each side of this central part is then thinned and drawn out sideways into projections, after which the work is folded at the central part round a tapering mandril of the section of the intended eye, and welded across the line of demarcation between the extended portions and the untouched tails. The tapering mandril is then again introduced into the hole from both sides, so that the handle when fitted and wedged in will hold it firmly. A slip of best cast steel is then inserted between the tails, as yet of their original size, up to the first weld, and all three are welded to the proper extent. The work is then put into a hollow fire, and the combined iron and steel drawn out sideways to the required width under the tilt hammer. The hatchet is then flattened and smoothed with the hammer; the edges are pared with the shears and trimmed with a round-faced hammer or top faller, the parings being afterward sent to the gun-barrel makers. After being ground on Derbyshire or Yorkshire stones it is glazed on a "hoh" or wooden wheel, covered with leather charged with emery. If not intended to be ground all bright, the part left unground is generally blued or black japanned. It is then "treed up" by the insertion of the helve or handle. For the handles of tools, $1\frac{1}{2}$ inch ash-wood planks are sawn into sheps by a circular saw, and the rough shapes turned in lathe, self-acting lathes being employed in the largest manufactories.

A New Rail Making Experiment.

At the Wyandotte rolling mill, at Wyandotte, near Detroit, Mich., recently, railroad rails were made of iron base and Bessemer steel head so successfully welded that the most trying tests failed to show even the joint of the juncture of the two metals. The same experiments showed the welded rail even better than the solid Bessemer steel. Each was submitted to 60 blows by a 20-ton hammer. The Bessemer rail was completely shattered, cracked through and through in every direction; the welded rail, though mashed down and twisted in the neck, showed no sign of a fracture in any part. The *Detroit Post* says this feat was accomplished by the use of a peculiar metalloid sponge or flux in the following manner:

The pile is made up as for the ordinary iron rail. For the head, scrap of steel, hitherto not utilized at all, are spread of the desired thickness, and upon this is laid a plate of steel. The flux, in the shape of hard substance about the size of a kernel of corn, is scattered through and over the pile, which is then placed in the oven. When properly heated, it is drawn and rolled in the ordinary manner. It is found to be a perfectly homogeneous mass; the fibrous iron, the crystalline steel, have their particles so interwoven that it is a physical impossibility to separate one from the other. Breaking or twisting does not produce a separation at the point of juncture. The wonderful work of uniting iron and steel, so mechanically different, into one homogeneous mass, is accomplished by the peculiar flux, composed of 55 parts iron, 20 parts silicon, and 25 parts aluminum. The chemical action of these substances is explained to be as follows: The silicon takes up all the alkaline matter, while the aluminum eliminates the free oxygen, phosphorus and sulphur, thus making a uniform, consistent, close-grained metal.

THE HILL CLIMBING ENGINE.—The novel contrivance known as the hill climbing engine continues to excite much interest in France. This engine, as described, has no wheels, and consequently does not roll, but in place of them is furnished with what are termed legs, upon which it accomplishes the purpose in view. It is like an ordinary engine in most respects, but is equipped with straight rods, terminating in broad circular skates. There are three of these legs in front and three behind. The cylinders, in place of actuating wheels, raise the feet. The apparatus is claimed to be especially adapted for carrying great weights up railway inclines. One of them, weighing 10 tons, is represented as running four or five miles an hour, and can accomplish $12\frac{1}{2}$ miles if desired.

A LONG RUN.—The Uniontown (Pa.) *Genius of Liberty* says: Dunbar furnace has "blown out" after a most successful blast of five years and six and a half months, during which time she has made 66,083 net tons of iron, including 6 per cent. of No. 1 foundry, 7 per cent. of No. 2 foundry, 79 per cent. of No. 1 gray forge, 4 per cent. of close gray forge, 2 per cent. of mottled and 2 per cent. of white. We believe that this is the largest blast on record of any furnace west of the mountains, and while some furnaces in the East have been in longer, we cannot recall as large an amount of iron made on a single blast.

Miniature Machinery at the Centennial.

In one of the ten by twelve wings of the Centennial machinery building will be exhibited a working model of a section of the Pennsylvania oil producing regions. The operation of erecting well-derricks, drilling wells, and of pumping and flowing oil wells, are illustrated, and a model of an oil refinery is shown, in front of which a small locomotive engine will be run with an attached train of Empire line oil cars, such as are used for the transportation by rail of the refinery product.

The other of the ten by twelve wings of the building is to be occupied by an exhibit designed to illustrate the important pipe-line interests of the Empire transportation company. An oil well and fixtures will be shown, together with a completely appointed pipe-line station in actual operation; also, a model of a pipe line, office, telegraph line, etc. The production of the model oil well is received at the pumping station, and forced through a line of pipe to a receiving tank located on an elevated portion of the counter adjacent to the railroad track. From this receiving tank the oil runs by gravity to a loading truck where a model tank oil car is loaded.

After the car is loaded it is then run to the other side of the building, where the oil is discharged into an underground tank, as is customary at the terminal delivery points of the Empire transportation company. On the six-foot counter, adjacent to the place where the oil is unloaded, there will be a small model exhibiting, in full and accurate detail, the arrangement of one of the terminal seaboard depots provided by the company for the extensive handling of crude and refined petroleum.

THE HUDSON RIVER BRIDGE.—The contract for the construction of the great Hudson river bridge has been given to the Keystone bridge company, of Pittsburgh. The general plan of the bridge is a suspended girder, with parallel and cradled cables, and two decks, one upon and one within the girder. There will be a great girder of wrought iron, 1,680 feet long, carried by wrought iron towers and cables of steel links and pins, the cables to be anchored in solid rock. On the upper deck is to be a double-track railway, and on the lower deck a carriage way of 16 feet in width in the clear. Each link of the cables will be subjected to a strain of 20,000 pounds to each square inch of section; the steel used in the links and pins is to have a limit of elasticity, without set, of 40,000 pounds to square inch of section of original area, and a final breaking strain of at least 50,000 pounds to the square inch. The towers are made of cells of wrought iron to the height of the tract of the railroad, which is to be 190 feet above high water; above the tracks there are to be eight columns, 11 feet in diameter and 80 feet high.

THE FIRST IRON PLANER.—The *Iron Trade Exchange* states that the first machine for planing iron was built by the elder John Rennie, in London. The following is from an original memorandum book of the late George Rennie: "In March, 1814, the following plan was adopted for chipping the cast iron sides of a new lathe. The sides are placed close together, with their faces upward; two planks of elm, one on each side, are bolted with their edges truly placed and upward; upon the edges of the planks run four wheels on axles, which support a truck of oak. To the truck is fixed a slide-rest, to which is attached a cutting tool; the truck is well loaded with weights, and pulled along the surface of the elm planks by means of a crab and chain. Thus the tool planes the iron lathe beds straight." This was, in fact, the first planing machine, crude and rude as it was, and from it Whitworth, to whom the original apparatus was shown, subsequently made a self-acting machine.

TO DRILL INTO HARD STEEL.—Make your drill oval in form, instead of the usual pointed shape, and temper as hard as it will bear without breaking; then roughen the surface where you desire to drill with a little diluted muriatic acid, and, instead of oil, use turpentine or kerosene, in which a little gum camphor has been dissolved, with your drill. In operating, keep the pressure on your drill firm and steady; and if the bottom of the hole should chance to become burrished, so that the drill will not act, as sometimes happens, again roughen with diluted acid as before; then clean out the hole carefully, and proceed again.

DISTANCE REGISTER.—A Scotchman announces the invention of a method of checking distance traveled by passengers in cars or wheeled carriages. It is described as a method which involves the use of a dial, provided, like an ordinary clock face, with hour and minute hands, the motion of which would be determined by the motion of the car, and at once enable both passenger and conductor to learn what distance the former had traveled when he wished to leave the car.

A BIG DIVING BELL.—A diving bell, 12 feet in diameter and 10 feet 6 inches high, was turned out of the Perseverance works, Deptford, Eng., and drawn by six horses to the West India docks for shipment to Barbadoes. It is intended to be used in the construction of new docks and breakwater.

SCIENTIFIC PROGRESS.

The Vibrations of Tuning Forks.

At the annual meeting of the National Academy of Science at Washington, April 20th, Prof. A. M. Mayer read a paper describing some ingenious experiments on the vibrations of tuning forks. It appears that tuning forks are now largely used for determining short periods of time, by means of apparatus involving their vibrations. Among these uses, one of the most prominent is in ascertaining the rate of flight of projectiles; another is for pathological experiments upon the rate and character of the pulse; still another is connected with telegraphy, both as to the absolute speed of the electric current and as to determinations of longitude. But the results obtained in these researches are slightly vitiated by errors of which the sources and laws have been as yet very little ascertained. It has been customary to ascribe the greater portion of these errors to differences of temperature. Instruments have been constructed at great expense to indicate the exact measure of time taken by tuning forks for their vibrations, but little certainly was obtained because of the difficulty of making the recording cylinders revolve, and the rest of the apparatus conform, with the needful accuracy.

Prof. Mayer has contrived an instrument in which variations of the rate of revolution of the recording cylinder do not affect the point at issue. He first fixes a pointed rod at the end of a pendulum (moved by a clock) so that the point, when at the lowest part of each beat, shall touch a globe of mercury. This touch to the globe completes an electric circuit leading to a tuning fork which is standing so close to a revolving cylinder that when the fork is vibrating a point on the fork describes a wavy line on the cylinder. (If the fork were not vibrating, it would mark a straight line on the cylinder when the latter is rotated.) At the instant of contact between the pendulum and mercury, a spark passes from the point on the fork to the cylinder. Upon the cylinder there is stretched a sheet of smoked paper, on which the wavy line of vibration is continually traced. When the spark passes, it goes through the paper. Two or three sparks may come with the contact, but only the first one goes through the paper. Thus the length of time between the beats of the pendulum is measured on the wavy line, and, as the number of waves in the line is the number of vibrations of the tuning fork, it follows that by counting the number of waves between each spark-hole, we have the number of vibrations of the fork in a given time, say a second. Evidently the rate of revolution of the cylinder is not concerned, as the only difference, whether that goes fast or slow, is to make the waves closer together or wider apart on the record; the number of waves remains unaffected. Prof. Mayer exhibited several of these records which had been fixed by dipping the blackened paper in a thin varnish.

Prof. Mayer first tested the correctness of the forks—which come stamped with a note that should indicate exactly a certain number of vibrations in a second. At 69 deg. Fah. he found only one fork in six was correct; one was three beats, another five beats, another 12 beats in 60 seconds out of the way.

MEASURING THE DEPTH OF THE SEA.—An ingenious instrument has recently been invented in England by Mr. C. William Siemens, for determining the depth of the sea without the use of a sounding line. Hung up in the cabin of a ship, it will at any moment indicate what is the depth of the water below. In an illustrated description of the instrument in *Nature*, the principle of construction is shown to depend on the variations in gravity which result from the interposition at sea of water, which has less attractive force than earth for a body on its surface. The attraction of gravity is determined by the density of the earth, which may be roughly estimated as about the average of surface rock, and about five and one-half times that of sea water. Consequently if a ship could be weighed in a spring balance, it would be found lighter when on the deepest water. In Mr. Siemens' device, a column of mercury is hung in a spring balance, and very delicate contrivances indicate the exceedingly slight differences in weight. It will give a notion of the delicacy of the instrument to mention that the record it gives for change of latitude is far greater than for sea depths, and has to be allowed for in calculation; of course this should be the case, since the earth is $26\frac{1}{2}$ miles thicker at the equator than at the poles. Tested by the soundings of the *Challenger*, the readings of the instrument have proved remarkably accurate. When the contour of the ocean bed is better ascertained, the means will thus be afforded to the mariner of ascertaining his position, by studying the indications of this index to the depth of water beneath him when the sky is too much clouded for observation. A contrivance for showing the difference in the earth's thickness by means of a weight suspended from a spring is figured in Herschel's "Outlines of Astronomy," but we are not aware that any practical use was made of it, if indeed it was ever constructed.

The Great French Reflector.

The great reflector of the Paris observatory is at last completed. Its mirror is of silvered glass, 1.2 meters (almost exactly four feet) in diameter, and with a focal length of eight meters, or a little more than 26 feet. The instrument is arranged as a so-called Newtonian—i. e., the observer is placed near the open end of the tube and looks into it at right angles to the direction in which it is pointed, the light being sent to the eye by a small flat mirror set at an angle of 45 deg. in the center of the tube. The performance is said to be very fine, but of this we can judge better when it works appears. The telescope is mounted in the open air, on an equatorial stand of peculiar construction, which from the figures looks as if it might be troubled by vibrations, as the polar axis, supported at both ends after the old English fashion, appears rather long and springy. The observer reaches his position by a sort of movable tower, which travels on a circular railway. When the instrument is not in use it is covered by a shed, which can be rolled off upon rails when not wanted. Only one reflector of greater power than this has ever been constructed—that of Lord Rosse, six feet in diameter. Three others have been built of the same size: the famous four-foot telescope of the elder Herschel (long ago dismantled), the great reflector of Mr. Lassell, and the telescope of the Melbourne observatory. Next to it rank among reflectors the smaller instrument of Lord Rosse, three feet in diameter; the instrument of the Marseilles observatory, which has a silvered glass mirror 08.10 of a meter (31 inches) in diameter; and that of Dr. Henry Draper, which has an aperture of 28 inches. The optical part of the Paris telescope is by Martin; the mechanical by Eichen. It is to be under the charge of M. Wolf, who will employ it chiefly upon the planets and their satellites. A gigantic refractor is also under way for the same observatory, to have an aperture of 30 inches; but it will be some years before its completion.

MICROSCOPY AT THE AMERICAN ASSOCIATION.—At the Detroit meeting of the American association for the advancement of science, last August, the microscopists who were in attendance decided to organize permanently an subsection or club, connected with the association. To allow ample time for preparation, and to facilitate the co-operation of all interested parties, it was decided to adjourn for one year, and to proceed with the organization at the Buffalo meeting of the association, which commences on the third Wednesday of August next, and continues about one week. All persons interested in the microscope, and desirous of joining such an organization as is now proposed, are invited to be present and co-operate, whether at present members of the association or not, and are requested to bring to the meeting original papers of scientific interest upon subjects connected with the microscope and its work, and also to bring instruments, accessories, and objects, especially those illustrating new or unfamiliar inventions, contrivances and discoveries.

THE SOLAR PROTUBERANCES.—For some time past the protuberances on the sun's surface have appeared less numerous. Father Secchi states the minimum is, however, not yet attained, and this is shown by the sudden changes in the phenomenon. On one day scarcely more than three protuberances can be found, while on the following day they may be counted by dozens, evidencing the fact that the solar activity in course of diminution suddenly, from some unknown cause, renews itself. Father Secchi also notes the rectilinear form of the hydrogen eruptions, which, with a thickness of several seconds, rise without deviation to a distance of two or three minutes (equal to 60 terrestrial diameters) from the sun's edge. The solar atmosphere is now so calm that the expansion, which takes place at the extremity of the incandescent columns, appears perfectly symmetrical on the two sides of every jet.

ATMOSPHERIC AMMONIA.—M. Schloesing has recently studied the exchange of ammonia which takes place between water and the atmosphere. The water which condenses in the clouds and which falls in rain would at first sight appear to despoil the air of all the ammonia contained. Such, however, is far from being the case. Sixteen analyses conducted at different temperatures show that the water never dissolves all the atmospheric ammonia. At 77 deg. Fah., the water takes up but 3 per cent. of the total amount of ammonia in the air; at 68 deg., 4 per cent.; at 59 deg., 6 per cent.; at 50 deg., 11 per cent.; and, finally, at 41 deg., 19 per cent. From this it appears that the lower the temperature the greater is the amount of ammonia dissolved.

NEW TEST FOR BORACIC ACID.—If a borate be finely pulverized in an agate mortar, and then introduced into an elongated loop of a platinum wire containing glycerine, and the mass is then held in the flame of a Bunsen burner for a few seconds, the glycerine will catch fire and burn with a beautiful green flame, leaving a carbonaceous residue. This test has been applied to over a dozen borates, and also to many minerals containing boracic acid, with perfectly satisfactory results. The students of the qualitative laboratory at the School of Mines, Columbia college, have used this test for two months with perfect success.

The Mining Share Market.

Mining stocks, although not unusually buoyant during the week, showed an upward tendency until Thursday, when a decided break occurred in the Gold Hill stocks. The temporary panic was confined entirely to Alpe, Yellow Jacket, Imperial and Overman. The balance of the list showed little difference from previous day's sales. In the Thursday morning board when Yellow Jacket was called there was a scene of excitement. At first everybody seemed to stand firm. Bidd began to unload the stock by the thousands. McDonald, Berry, Sobmedell and scores of others threw huge lots away. The stock broke to \$38, and would have gone much lower had not Keene stood in to the rescue. Marshaling his forces about him, he tipped the wink to his brokers, and they set to work with such a will that the downward movement was checked, and the stock began to mount the ladder step by step. Over six thousand two hundred shares changed hands during the panic. Another terrible fight was made over Imperial. The price was beaten back to \$55—over 11,000 shares being started right and left. The rapid depreciation in the Gold Hill stocks came like a thunderbolt upon outside dealers, and there was great trembling lest "more mud" would have to be forthcoming.

The Trojan mining company are in trouble with their Treasurer, John W. Pearson, who, it is asserted by the stockholders, or a portion of them, has been extremely lavish with the money of the company, raised by a series of assessments, the first of which was 50 cents a share, amounting to \$50,000, and the last 60 cents a share, amounting to \$60,000. A meeting of stockholders was held this week, when they appointed a committee of three to demand a complete statement of the cost of constructing the works, and with instructions to make a full and complete investigation into the books and accounts of the company.

The dividend paid by the Northern Belle mining company is the twelfth, making a total of \$600,000, all of which has been disbursed within a year. Stockholders have received good interest for their money.

The two bonanza mines are now yielding at the rate of 10,000 tons of ore per month, producing in the aggregate about \$5,000,000 in bullion, 40 per cent of which goes to stockholders.

The new stock of the Hale & Norcross mining company is now ready. An assessment of \$1.50 per share on the new stock has just been levied, amounting to \$168,000, 100 per cent. more than need to be levied, delinquent June 21st.

The members of the Pacific Stock Exchange took possession of their fine new stock rooms this week, on Montgomery street, opposite Nevada block.

E. P. Heamer, the Secretary of the Amazon and Glasgow mines, has gone out of the city, leaving the above companies to mourn his departure for reasons of a financial nature.

The Consolidated Imperial mining company held its first annual meeting on the 13th inst. The company now control the interests formerly represented by the Beacon, Consolidated Gold Hill Quartz, Eolipse, Empire, Imperial and Trench. The trustees elected were A. K. P. Harmon, J. D. Fry, C. L. Weller, James H. Robinson, William Norris, Joseph Sharon and Alpheus Bull. Subsequently A. K. P. Harmon was chosen President; W. E. Dean, Secretary; and C. O. Batterman, Superintendent.

The stock of the Virginia gold and silver mining company has been listed on the San Francisco board.

The Government has decided to become a bidder at the sale of Harper's Ferry property, which is advertised to take place on the 20th of June next, at Harper's Ferry.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MINING NOTES.—Amador Ledger, May 13: There is considerable activity displayed in mining matters beyond Volcano. Mac's mill is now kept running eight and a half days on rock from the claim of Irving Brothers. The small vein of very rich ore struck in the Modoc, to which we referred a few weeks ago, continues to yield up its wealth. They are now following the vein from the top of the tunnel toward the surface, and the ledge has widened from eight or 10 inches to 20 inches, so that a piece of rock can be picked from the dump that does not show free gold. We hope in a short time to be able to chronicle the result of a crush from this golden thread. Daas & Barron's mill, near Pleasant Grove, is also kept running steadily, with encouraging results.

BELDEN MINE.—This mine is situated in the northern portion of the county, and has been idle for some time. With the revival of the mining interests generally in that locality, this claim has also been brought within the stimulating influence. The Bowers Brothers and J. Ryerson have obtained control of the property, and have started running in a lively manner. After running a tunnel into the hill, they struck a quartz lead, and at last some prospecting has been done. The results obtained from the rock are very satisfactory. Encouraged by their success the boys went to work and leased the old Belden mill, in the same locality. They have crushed quite a quantity of ore, which yielded an average of \$18 per ton. To all appearance the rock is there in unlimited quantity, and it is the intention to keep the mill constantly running.

FRANK'S MINE.—Probably the richest quartz vein of its size now being worked in the county is that of Frank's mine near West Point bridge. The mill is going all the time, and every clean-up fine manages to pocket a miniature fortune. The ore is fabulously rich, some of it reaching up in the hundreds. It averages about \$30 per ton, and from this some idea may be formed of the stream of wealth which is poured into the pocket of the fortunate owner.

THE BONANZA MINE.—A correspondent at Drytown sends us the following concerning this property: The work of taking out ore has been unimpeded for the last two weeks, on account of sinking a new shaft. It is reported around Drytown that the mine will probably be sold before long. Mr. Oliver, a mining expert from the East, has been inspecting the property lately, which has given color to the rumor that it is likely to change hands. The claim has paid well so far, and the indications are that it will prove a permanent mine.

LIVELY TIMES.—Fiddletown is lively, business brisk, and the people happy. Several new buildings are in process of construction, and the mining interest is booming. Just now it is intended to bear the palm as the most prosperous camp in the county. Several claims besides those of the American Fret gravel company are being actively prosecuted, with very fair results. The company clean up every now and again, and although little is noised abroad about the amount of gold realized, yet it is generally conceded to be satisfactory.

THE MARION MINE.—Amador Dispatch, May 13: This mine, at Sutter Creek, which we have been following for some time, has been leased to Stewart & Co., and we are informed that work will be immediately resumed on the same by the lessees.

DISPUTED CLAIM.—About two years ago Robt. Fredly, familiarly known as French Bob, then living in Sutter Creek, commenced driving a tunnel into the hill close to the road, near Amador City, as it was thought close to it not far from the Keystone camp. About a month ago, however, after running into the hill a distance of about sixty feet, he was ordered to quit by the managers of the Keystone. Bob says the ledge shows between five and six feet in width, and prospects well. The reasons for the company's embargo upon the further prosecution of work we are unable to give, but, as might be expected, Bob feels bad at being compelled to sacrifice two years' toil just at the time when he thought fortune was within his grasp.

CALAVERAS.

LIVELY TIMES AT MOSQUITO.—Calaveras Chronicle, May 13: Times are said to be lively at Mosquito Gulch, consequent upon the successful working of numerous quartz mines in the district. Butting is going rapidly forward, hotels are multiplying and business all descriptions is brisk. J. L. Hoye Esq., is putting up a saloon that for elegance of finish, sumptuousness of furniture and fixtures, and beauty of surroundings, can't be beat outside of San Francisco or Mokelumne Hill. Mosquito is the liveliest camp in the mining section of the State, always excepting the boss town, of course.

STARTLING MINING NOTES.—At West Point Haskins & Hadley, proprietors of the celebrated Champion mine, are crushing in Carlton's mill. They will put about 100 tons of ore under the stamps and expect to clean-up the largest amount ever taken from a single crushing in the upper country. At Mosquito, Hadlock has 30 tons of rich ore in readiness for the stamps. A contract has been let to sink the San Bruno shaft 100 feet deeper. Champion, Dunston & Co. are the contractors. A pump is being put into the shaft, hoisting the water in buckets being found too tedious a process. The Grasshopper continues to yield unprecedentedly rich rock. The damage to Gerleard's mill caused by blowing out the cylinder head will be repaired the first of the week. Rock from several mines in the vicinity is in readiness for crushing.

THE BRADY MILL & MINE.—Saturday last we visited the Boston company's mine near Buckeye, better known, perhaps, as the Brady mine. The work of putting up the mill—one of Cooper and Cowles' Giant crushers—is about completed, it being expected to have the machinery in running order next Monday morning. Very general interest is felt in the result of its working, and should the Giant crusher realize what is claimed for it by its inventor it will greatly promote and stimulate quartz mining. The result of the operation of the mill at the Brady mine will be taken as a criterion of the merits of the new process, a fact that invests the trial with a good deal of interest among mining men. The prospects of the mine are widely favorable. The ledge, an immense one by the way, crops out boldly at the base of a mountain, obviating the necessity of sinking shafts or running tunnels in obtaining ore. Thousands of tons of quartz can be mined without penetrating the hill at all, at a merely nominal expense. The mill being situated close to the ledge the expense of transporting ore is entirely avoided. In fact, if it could be ordered, better facilities for working to advantage could not have been obtained. The rock looks and prospects well. Nearly all of it carries sulphurets, and free gold is frequently visible. Good judges are of the opinion that the entire ledge can be profitably mined.

COLUSA.

QUICKSILVER MINES.—Colusa Independent, May 13: Although Colusa county is included in the list of agri-

cultural or "cow" counties, we still have some mineral wealth. It has been said that this production of quicksilver is likely to become one of the most important industries of the State, and we do not hesitate to assert our belief that there is enough quicksilver ore in this county to supply the markets of the world for the next 10 years. We had the pleasure one day this week to visit the Last Chance, Juniper and Kentucky mines in the western part of this county. The two last named mines, though rich in ore, are not being worked at present, but the Last Chance, under the management of the Rathbun brothers, is turning out some splendid ore. This company has prospected its mine quite thoroughly, and there is no doubt but it contains an almost inexhaustible quantity of exceedingly rich ore. They have two retorts at work, but no furnaces; and we were told by Mr. Rathbun that they had turned out as much as 400 pounds of quicksilver at a single reduction. They recently assayed a new lead at the north end of the mine, and had struck a vein of black or purple powder ore, that was richer than anything hitherto found. It is literally saturated with quicksilver, and by panning it out one can almost get the pure metal.

EL DORADO.

MOUNT PLEASANT MINE.—Mountain Democrat, May 13: As many of our readers are aware, the Mount Pleasant is situated near Grizzly flat in this county. It is owned by O. D. Lambard, and Wm. Teague is the superintendent. Recently the prospecting has been done to a portion of the mine in which a rich and extensive development has been made. We are informed that this development is constantly increasing in quality and extent. Latest advices report a ledge fully eleven feet in width, of which a large proportion is very high grade ore.

A L. 49, last Wednesday, we got a glimpse at a fine full sized ledge. It had been picked up by A. J. Blakely during the preceding week at his claim on the old "Johnson ranch," some five or six miles above this city. The ledge of the nuggets weighed \$28, and there were several of half an ounce to an ounce in weight. The gold is of superior quality. On the same day Mr. Blakely sent down about 30 ounces of fine gold to the mint for assay. The gold has been taken from the ground about which Blakely and Johnson were so long in litigation, the latter claiming that there was no gold in those grass roots.

THE ROZEKREANS.—We are in receipt of highly flattering information from the Rozekrans mine, which is situated near Greenwood, in this county, and is an extension of the Taylor mine. Our information is furnished by an old friend, a miner of large experience, who has no interest direct or indirect in the mine referred to, and who could have no possible motive for misinformation. He visited that mine last week, and reports that the ledge has widened until it now ranges from seven to ten feet in thickness. In looking through several tons of ore he could scarcely find a piece which did not show free gold visible to the naked eye. The ore is heavily laden with rich sulphurets. Our friend is a practical assayer. He assayed several samples of the sulphurets which he picked up at the Rozekrans. The results ranged from \$800 to \$1,500 per ton from these same sulphurets. Our friend very confidently predicts that the Rozekrans is destined to recognition as an extraordinarily rich mining property.

THE ST. LAWRENCE.—Messrs. Alderson & Milson are making active preparations for recommencing operations at the St. Lawrence mine, near Grizzly flat. They are putting in a new six-inch pump, with which they propose to sink until they can reach the old pump which was left in the mine when the old company quit work. If, when they get down to where operations were suspended, they find that the shaft has not caved in, they will immediately proceed to sink deeper; otherwise they will be compelled to re-open it, which will of course entail some delay. The shaft was down about 800 feet, we believe, when the old company quit work. Miners who were then at work there say that at that level the north drift was in splendid ore, not very wide, but rich, and at the bottom of the shaft there was every indication that the ledge was coming in again.

MINING ENTERPRISE.—Near the mouth of Kelley canon, a short distance below Chile Bar bridge, a fine quartz property is in course of development by a company of experienced miners from Amador county. It is on a ledge which was superficially prospected many years ago by the Willets brothers. The present owners are sinking a four by eight shaft and have gone down about 40 or 50 feet, at which point the ledge is about three feet thick, between walls of granite and slate. The ore is liberally sprinkled with free gold, and the appearance of the ledge is extremely promising.

FRESNO.

NE PLUS ULTRA.—Fresno Examiner, May 13: This company has recently filed its certificate of incorporation. The principal place of business is Fresno. We understand that a portion of the capital stock will be offered for sale in order to acquire a working capital. The Ne Plus Ultra is probably the richest copper mine ever discovered in the State, and we are glad that it has at length been taken into consideration. It can be properly managed, and we shall be surprised if speedy arrangements are not made for developing the mine.

INYO.

LOCAL MINING SUMMARY.—Coso Mining News, May 13: The Lookout mines are developing to an extraordinary degree, fairly astonishing their lucky owners in the immense deposits, or rather huge veins, and the quantity and richness of the ore extracted. From C. J. Barber, the superintendent, we learn that the confidence is looking better every day. The main drift is now in 165 feet, every foot of it being run through the very best of ore. At the face of the tunnel the character of the ore has materially changed, and high grade milling ore, freely interspersed with horn silver, is now being taken out. About 20 feet from the face of the drift, the ore is now being started at the face of the drift, and through the whole distance, without a pound of waste, there being no sign yet of the hanging wall of the ore body. About 50 feet from face of drift a raise has been started and a height of 30 feet has been reached, all through the same high grade class of ore. On the Lookout a drift has been run to the right of the old one and is now in 50 feet through ore all the way, with the exception of a few boulders. At the face of drift the ore vein is 16 feet wide and all ore, two men taking out five tons per day. Assays made daily of the ore dirt run from \$160 to \$300 per ton. The new wagon road is now so near completion that wagons from Darwin run to Minute Gun spring, distant from Darwin about 10 miles and from the mines about 20 miles. The ore is excellent, and the development made within the last two or three days on the Veteran, a mine owned by Archie McDonald, on the last inst. The mine is an extension of the Confidence, the bonanza vein of the Modoc company. A splendid body of high grade ore has been developed, some 25 feet from the mouth of drift, over four feet in width, and is constantly increasing in quantity and quality as the work is prosecuted.

DEFIANCE FURNACE.

Has been running very well during the week, and the company have shipped 622 bars, there being 70 bars on hand. The foundation is now being laid and the building enlarged for the accommodation of furnace No. 2, most of the machinery for which is now here. It will probably be running within a week.

LOS ANGELES.

JUMPING.—Los Angeles Express, May 13: We learn that the claim of the Los Angeles coal company, in the San Fernando mountains, about 30 miles from here, was jumped last Sunday by a party of men who are still in possession of it. The facts, as they come to us, are these: Several months ago this company discovered cool indications in the place designated, and at once

located their claim under the United States laws. They incorporated as a company, had the land surveyed and regularly filed, and placed several men at work. The work was progressing very satisfactorily, and to a depth of 25 feet in the shaft a very superior prospect of coal was found. Last Saturday the company purchased a large amount of supplies, engaged several additional men, and started them out to the mine on Sunday. On arriving at the mine on Monday morning, they were confronted by 10 men armed to the teeth, who warned them off, and claimed the mine as theirs. As there was not force enough to cope with those who had jumped the claim, Dr. Keweenaw, who was in charge of the company's party, set the men at work sinking a new shaft near the old one. They have been at work there ever since, while the jumping party are resting on their arms, guarding the old shaft. Some of the men who are operating with the jumpers are members of the old company, and owned interests in the mine, but they with the others were there for the purpose of working the claim and holding possession for the company, and were kept in supplies while there by the company. The whole matter will doubtless be carried into the courts.

PLACER.

MINING ITEMS.—Dutch Flat Forum, May 11: Everything has been under full headway for the past week, except the usual accidents and delays incident to mining in general, and hydraulic mining in particular. The three ditches are conveying all the water desired by the miners, who are making every effort to recover the time lost by the protracted storms and deep snow. The Elmore Hill, Polar Star and Boston claims are running as contentedly as the quality of the gravel will permit. The Central, Duane, Pacific and Jehoshaphat claims continue washing.

The Yankee and Badger were washing until Saturday morning, at which time the Yankee shaft became plugged by an old drift timber, and every effort to reach below, causing the boulders to dem back, shutting down both claims for two days. The Yankee cleaned the sluices in tunnel below on Monday, refitted Tuesday, cleaned up the sluices about yesterday and resumed washing last evening. This we call quick work, as there are in all about half a mile of sluice boxes. The Franklin has been attempting to have its incline plugged Tuesday morning, about half an hour after turning on water.

AT GOLD RUN.—The Cedar, Indiana Hill, Gold Run, Sachs and Hoskin claims are washing. The two former are rapidly working down toward the bedrock, much to the gratification of the miners of their vicinity, who are anxious to see the bed of the ancient channel exposed. The Indiana Hill mine, a branch of the company, of Gold Run, cleaned up over \$5,000 a few days ago, the result of a short run.

YOU BET MINING ITEMS.—The Red Dog claim works 14 men, and is using 800 inches of water. In the Waloupa five men are employed, and 800 inches of water used. In the Nece and West 28 men are employed, and 200 inches of water used. All the above claims are under the superintendency of G. S. Powers. Regular clean-ups have been made in the above claims this season with satisfactory results. The superintendent is under full headway with a full force of men, and comes over frequently with a good showing of amalgam, the best indication in the world that his claims pay. The Chalk Bluff, under the superintendency of Dr. Keweenaw, is pushing work right along with a full force of men.

SHADY RUN ITEMS.—We learn that Capt. Anderson's claim is now paying splendidly and the prospects brightening as they advance with the work. The sluice boxes of Wedgewood, Corlett & Brink's claim were robbed on Monday, May 1st, 1876. Supposed to be the work of a couple of Chinamen, who were afterwards seen there afterwards, but no evidence to convict them was obtainable and they were allowed to depart.

SIERRA.

NEW MINING ENTERPRISE.—Mountain Messenger, May 13: The Red Dog, at Red Dog, has been mining ground between the town and the Yuba, an ancient bed of the river, and will work it with their derrick, having succeeded in lessening an abundant supply of water for all their purposes, for the next two years, of the Rock Creek ditch company. They have 20 Chinamen now at work on their diggings. All of the adjacent ground paid fabulous sums in early days, and now, when no one knows where to dig, the value of these claims should not be equally remunerative. Heretofore this ground has been divided into separate claims, and as the owners failed in coming to any agreement necessary for working the same, they remained idle. But now that they have been consolidated under an able and energetic management, great returns may be expected at the early day. The White Sulphur mine, near the dawn of another golden era for Goodyear, whose brilliant record in the historic days of '52 has seldom, if ever, been eclipsed by any California mining camp.

BU-X.—Berry is putting in new sluice boxes this week in his "graveyard" mine, which, as near as we can learn, promises good returns.

PARLIES.—Parlies have discovered good gravel diggings on the East fork above Ben Paul's saw-mill. One piece, worth \$25 or \$30, is shown, together with considerable fine gold.

SISKIYOU.

RUNNING.—Yreka Union, May 6: A. M. Johnson's quartz mill has again started up, during the week crushing rock from his ledge, and he expects to have enough water to keep it running right along.

Johnson now has some 25 men to work at the mill and, from all accounts the rock pays first-class, and this mine is considered by many to be as rich as any discovered. This property is situated on the divide between Quartz valley and Scott valley, and there are numerous other ledges around it that will also pay well when opened.

SOON RESUMED.—Work will soon be resumed at the old mine in Trinity valley. Now that the roads are opened so that provisions, etc., can be got to the mines, a large number of men will find employment there. The Alcona company have a bunch of five large retorts, already set for work, and the superintendent intends to erect two furnaces for lower class ore as soon as the weather permits. The other companies will push the work of opening their mines with increased vigor, and ere the summer is over there will be mines as rich as the Altona in hill blast.

MR. W. A. FARISH has left the Black Bear mine in charge of Mr. Johns, the new superintendent, and is looking around Siskiyou a little before starting below. The last month's clean-up at the Black Bear surpassed any other made by several thousand dollars, and it fairly made a man's mouth water to "helt" the gold brought over the mountain on Monday last. It took six Indians to peck it over the snow, and they had no very light loads then.

Nevada.

WASHOE DISTRICT.

ORIGINAL COMELOCK.—Gold Hill News, May 11: The lower tunnel is being pushed ahead with energy, and is already well started into the hill, from the ravine. Being run nearly parallel with the main vein, it must soon intersect it, after which it is proposed to follow the foot-wall, occasionally cross cutting for ore development and working. This tunnel will open the ledge to a depth of 200 feet. Meanwhile the new working on the hill has also been started to develop the ledge to a much greater depth, is making excellent progress.

SOUTH COMELOCK.—Owing to increase of water and other adverse circumstances, work is suspended in the mine until heavier machinery can be brought to bear in the case. This is being contracted for.

FRONDA.—Much difficulty is experienced in cleaning out the mine at the 400 ft level, on account of the large amount of water encountered, but the work is pushed

ahead as lively as possible, the pump doing excellent duty. A good air pipe is put in and the situation is getting pretty well under control. This water most undoubtedly comes from the main ledge or ore channel, which has not yet been fully explored, but merely cut into or tapped by the drift. The 300-ft level drift is impeded by similar trouble.

NORTH CARSON.—The erection of the new hoisting works is about completed, and they will be ready to steam up very shortly.

CROSBY CONSOLIDATED.—The north drift on the 300-ft level is now in a distance of 81 feet, and it is the intention to cross-cut and ascertain the width of the ledge when the drift has reached a point 200 feet north.

DAYTON.—Sinking the main shaft is going rapidly ahead, the bottom in good sinking ground. The east drift, on the 700-ft level, is rapidly approaching the ledge.

DAY WASHINGTON.—The repairing and easing up of the shaft timbers, necessitated by the swelling of the vein matter near the bottom, is completed, and sinking is resumed at the rate of nearly four feet per day. Splendid ore indications are being passed through, with no increase of water.

MINT.—The shaft is now down 1,080 feet, the bottom again in soft ledge material. The flow of water is still light.

CONSOLIDATED VIRGINIA.—Daily yield, 600 tons of ore. The ore breasts are both looking and yielding well. The ore shows no depreciation in value, and the prospects of the mine appear to be as good as they have at any time during the past year. The usual monthly dividend of \$2 per share, aggregating \$1,080,000, was paid on the 4th inst., and a surplus carried over sufficient to make another such, if the management so desired. The east drift on the 1500-ft level is now well advanced toward the C. & C. shaft, which is now down almost to the point at which it is the intention to open a station to connect with the drift. The most important feature in connection with the mine for the past week, however, has been the starting up the north drift on the 1700-ft level of the Best & Belcher mine, to cut and prospect the Consolidated Virginia ore vein. This drift will cut the ledge at a depth of nearly 200 feet below the present workings, and will penetrate nearly 100 feet lower down than the bottom of the winzes sunk below the 1550-ft level of the Consolidated Virginia and the California. The developments to be made by this drift will be looked forward to with deep interest by every person having or taking an interest in the Comstock lode. The erection of the new Consolidated Virginia amalgamating mill, and the new 80-stamp mill east of the C. & C. shaft, is going rapidly forward. The foundation timbers are being framed, and much of the machinery for each is already on the ground.

CALIFORNIA.—Daily yield, 360 tons of ore, keeping the California and Sacramento mills steadily running. The ore breasts were never showing richer than at present. Laying the foundation sills for opening out more extensively on the ore body is going rapidly forward. The first dividend of this mine—\$2 per share, aggregating \$1,080,000—was declared on the 8th, payable on the 15th inst. This is but the beginning of millions of dollars that the mine is to yield for the next two or three years to come, which will place the California side by side with her twin sister, the rich and prolific Consolidated Virginia. Had the company the mills with which to crush their ore, no effort whatever would be required to take out and mill ore sufficient to produce \$3,000,000 per month. The north winze, below cross-cut No. 6, has reached the 1600-ft level, at which point a drift is being run to connect with the Ophir shaft for ventilation purposes. On the 1400-ft level the north drift is being steadily pushed ahead to connect with the Ophir. Sinking the C. & C. shaft is making fair progress notwithstanding the strong, steady flow of water at the bottom.

OPHIR.—Daily yield, 150 tons of ore, keeping the Winfield, Empire State and Nevada mills all steadily running. The ore breasts on the 1600-ft level going steadily toward the California line are yielding rich ore. The stopes at that point have about 140 feet to be cut yet to reach the line. The north drift on that level running toward the Mexican ground is making excellent progress. The blasting in this drift is being done by means of Burleigh drills. On the 1700-ft level the north drift is also being advanced to cut the ore vein at a point under where the fine ore discovery was made in the Mexican lode on the 1455-ft level. The main southeast drift on the 1100-ft level is steadily advancing, the face still in quartz of a good description. The upraise from the 1300-ft level is in ore, and is making good progress. The fourth compartment of the main shaft is completed down to the 1600-ft level. The new office building is ready for occupancy, and everything in and about the mine is in excellent working condition.

NORTH CON. VIRGINIA.—The shaft has reached a depth of 800 feet, at which point the sinking has been suspended for the purpose of cutting out a station and putting in a large water tank. It was decided that the shaft had reached a depth at which it was necessary to put in pumping machinery that will drain any sudden heavy flow of water that may be encountered. This is a good move in the right direction, for should a strong body of water be struck the present appliances would never suffice to keep it down. The plans and specifications for the new shaft have already been forwarded, and the machinery will be manufactured in San Francisco and forwarded at the very earliest possible moment.

PHIL SHERIDAN.—The new machinery is all in place and working splendidly. It is sufficiently powerful to sink the shaft with ease to a depth of 1,200 feet or more. The shaft is now being put in good working condition, and in a very few days the water, of which there is about 30 feet in the bottom of the shaft, will be drained.

JULIA.—The south drift on the 1600-ft level is developing a better character of quartz and ore every day as it progresses farther to the southward.

OROVN POINT.—The ore vein on the 1600-ft level has been thoroughly prospected to the Belcher line, without finding any paying bodies of ore. A drift is now being run east on that level, near the center of the drift, with the view of fully determining whether there is any split or division of the vein in that direction.

BROOKS.—Rapid progress is being made in sinking the main shaft. The ledge material at the bottom is very favorable. As soon as the shaft has reached a depth of 200 feet a cross drift will be run to ascertain the width of the ledge.

JUSTICE.—Sinking the main incline below the 1000-ft level is going steadily forward, the bottom in good working ground. The north drift on the 800-ft level is now being advanced, and the prospects that have been found north of the shaft since the discovery of the rich streak of ore found north on the 300-ft level. A cross-cut east has been started from this drift which also has some excellent ore prospects.

GLASGOW.—On the 300-ft level the main north drift has penetrated a body of ore 20 feet, the entire face of the drift being in ore of a good quality. The ore seems to be mainly sandstone and quartz, and the indications are that the drift has cut the apex of a large chimney of ore. A winze will soon be started to test the ore vein below this 300-ft level.

WARD.—Sinking the shaft is making excellent headway, the bottom in good working ground. It is now down 90 feet. Occasional seams of quartz are encountered, and the drift is being advanced yesterday a streak of quartz 18 inches thick, which gave an assay of \$28 per ton, was struck in the shaft.

AMAZON CON.—The ore developments so far on the 300-ft level are very encouraging. It is intention to shortly commence the sinking of the main shaft for the purpose of opening a new level.

CRAN.—The usual amount of good ore is being extracted from the stopes on the tunnel level. The

drift north on the 300-ft level is in good ore. The water in the main incline is rapidly receding.

OVERMAN.—The upper or 900-ft level has been opened and about 30 tons of ore per day is now being extracted from the ore body struck in that portion of the mine a year ago or more.

GOUIN & CURRY.—The foundations for the pumping machinery are being pressed to completion with all possible vigor. The old carpenter shop on the south side of the shaft is being removed, to make a sufficiency of room.

BULLION.—The drift on the 2000-ft level is steadily advancing, the rock in the face gradually softening and showing signs of a nearer approach to the ledge.

SUPERIOR.—The flow of water is quite strong, and is steadily on the increase. New machinery has been contracted for, and it is expected will be on the ground ready for use by the first of next month.

CHOLLAR-POWELL.—Daily yield 90 tons of ore, the assay value of which is \$33 per ton. Sinking the main incline below the 1350-ft level is progressing at the rate of two feet per day.

PROSPECT.—Twenty feet has been added to the depth of the shaft this week. The depth is now, 220 feet. Another Ingersoll drill will arrive from New York in a day or two and be put to work in the shaft.

YELLOW JACKET.—Sinking the north winze below the 1940-ft level has been resumed. Cross-cuts Nos. 3 and 4, on the 1040-ft level, are showing good prospects. The north and south drifts in the ledge on the same level are also looking more favorable.

EXPRESS.—The north drift on the 2000-ft level still continues in good ore. A chamber has been cut out and a winze started downward on the ore vein near the north line. The ore in the bottom of this winze is still showing rich ore.

BELCHER.—Daily yield, 450 tons of ore. The ore breasts are all looking well and yielding the usual quantities of good milling ore. The foundations for the new pumping machinery are rapidly approaching completion.

UTAH.—The flow of water at the bottom of the main shaft is strong, but can yet be readily handled with the pumps.

SILVER HILL.—A new station is being opened at the 500-ft level of the incline. While opening the station it has been found necessary to suspend the sinking of the main incline.

WEST BELCHER.—The west drift at the 226-ft station is in 240 feet. The northwest drift on the same level is in 138 feet. The faces of both drifts are still in low grade ore.

HALE & NORCROSS.—The work on the foundations for the new pumping machinery is going steadily forward. The machinery is arriving on the ground daily.

EAST OVERMAN.—The shaft is in good working ground and is cutting stringers of quartz that give valuable assays.

PICTON.—Branches and streaks of pretty fair ore have been cut through by the drift this week, showing that something good may be expected when cross-cutting through the ledge.

CEMOPOLITAN.—The raise above the main adit tunnel was up 144 feet last evening, following the inclination of the ledge in good ore.

ROCK ISLAND.—The north drift on the 850-ft level is showing a very encouraging improvement; also the west drift on the same level.

TROJAN.—The new hoisting works and machinery are all completed and ready to start up as soon as a mud drum for one of the boilers arrives.

KOSSTER.—The water is reduced to below the 350-ft level. The drifts on that level were but little damaged by the water.

SUCOR.—Sinking the main shaft is going ahead steadily. The flow of water is still strong.

LANT BAYAN.—The foundations for the new machinery are being laid as rapidly as possible.

UNION CONSOLIDATED.—The quartz in the face of the north drift on the 1300-ft level is still showing finely.

ALTA.—Laying the foundations for the new and powerful pumping machinery is making excellent progress.

REN & WHITE CROSS.—Negotiating for new hoisting works for deeper sinking.

(Continued on Page 332.)

Steamboat Sulphur Beds.

A week or two since a reporter of the Gold Hill News visited the recently discovered sulphur beds, situated at the base of the mountain, one and one-half miles west of Steamboat springs, in Washoe county, and from a personal inspection of the mines and surrounding country, is enabled to give the following facts and conclusions: The sulphur belt was discovered a few months since by Thomas Wheeler and Isaac Spencer, of Reno, who were prospecting in that section for cinnabar. The deposits have been opened by cuts and shafts at different points, extending north and south for a distance of half a mile or more. The sulphur is imbedded in a light colored, chalky appearing formation, strongly resembling slate, which formation is half a mile in width, and can be traced northerly and southerly for at least a mile, and, judging from the general surface appearances, it is reasonable to suppose underlies the whole extent of the magnesium formation. The sulphur has been found in most of the shafts and cut a very few feet below the surface. On the surface no escapes or indications of heat are visible, but in all the cuts and shafts great heat, steam and gas have been developed a very few feet below the crust. The principal claim, known as the Wheeler & Spencer, has been leased to James Duffly and Thomas Smith of Carson City, for a term of three months. These gentlemen have commenced the opening of the sulphur deposit on a point of the mountain, some 150 feet above the level of the flat, having secured for a foreman of the works the services of Mr. Joseph Scott, who is probably the best posted sulphur miner and prospector in the State. Mr. Scott opened the famous Rabbit Hole mine in Humboldt county, and has been a steady prospector in that line for several years past. The mine at that point has been opened to a depth of 20 feet by running open cuts into the hillside wide enough in which to turn a horse and cart. The cuts show the sulphur to lie in crystallized bunches and streaks, intermixed through and through the talc, or magnesian bed. Five or six tons of sulphur had been extracted, and lay piled up ready for shipment, and some fifty tons more were stripped, almost ready for extraction. At the bottom of the pit the heat was great enough to ruin the soles of a man's boots who would dare to linger there any length of time, and the sulphurous gases and steam made it a very uncomfortable place in which to labor. The appearances show, beyond a doubt, that a large and paying deposit of sulphur has been found. The sulphur, in its raw state, just as it is extracted from the mine, assays about 75 per

cent. of the pure article, and is worth in the San Francisco market \$50 per ton. These beds are within easy reach of the railroad, and if it is desirable a side track can be easily constructed almost to the mines.

These hot, steaming beds of brimstone undoubtedly furnish a natural clue to the causes that operate the famous Steamboat springs, a mile and a half to the eastward. The formation underlying the sulphur beds is undoubtedly an immense ledge of magnesian limestone, filled with veins of iron, sulphur, and other minerals. Immediately in front, and overlying this bed of minerals, is a mountain of hard, syenitic granite. Back of it the mountain rises quite abruptly, and there is but little doubt that some of the small lakes formed by the melting snows on the table lands above find outlets through the open rocks into this bed, thus producing a decomposition of the minerals and releasing the carbonic acid in the limestone, which creates the powerful heat of the springs. The minerals are thus sublimated, and afterwards condensed by the cold near the surface and left in the state in which we now find them. The first dip of the stratum, at the base of the mountain, is quite steep, and the flow of water following the strong inclination of the rocks evidently passes underneath the belt of syenitic granite in front, and finds an outlet through the fissures and seams in the soft rocks beyond. The damming or closing up at times of these escape valves no doubt often confines the sublimated minerals and superheated steam to such an extent that it is forced to the surface with great power, which readily accounts for the mysterious exudation of the sediment and water which so often takes place so forcibly, and has attracted so much attention from visitors.

Tuolumne County Mining Interests.

Of late years but little attention has been paid to quartz mines in our county, and yet they are destined to become famous, and that at no distant day. We can look back and see where, in different locations, hundreds of thousands have been squandered recklessly and foolishly. Mines which under careful and judicious management would have yielded splendid returns to the shareholders are now abandoned. But a new era is dawning upon us. Already we discern signs of regeneration. The different processes which we have from time to time brought before our readers are gradually assuming definite shape. We hear of the Fryer process soon to be in operation at the Waters claim, and the Lightning amalgamator (patented by Walker & Co., of Philadelphia) will shortly be on a mine in the immediate vicinity.

At the Consolidated Alabama mine, Cowles & Cooper's Giant mill is in active operation, and bids fair to surpass all other mills in the reduction of ore. Inexpensive as it is, and effectual in its working, there can be no doubt but that it will be adopted by a great many of the mines which have been unable to work to a profit with the old stamp mills. At this mine, which is justly attracting considerable notice, there has just been completed one of Schofield's concentrators, which is far ahead of anything of the kind now in use. It needs no prophetic eye to facilitate an early commencement of dividends to the shareholders.

A short distance from the above, the mines owned by Messrs. Hayward and Rosbury are situated, and it is probable that they will soon begin operations on a large scale.

The Raw Hide, adjoining the Alabama on the northwest, one of the most celebrated in the State, lies idle. Half a million has been spent here, but through the folly and reckless disregard of the superintendents and others in charge, the managers were reluctantly compelled to cease all operations. It is expected that they will soon start again with one or another of the new processes, and it cannot but prove largely remunerative to the owners.

We may be in error, but we predict that within the next twelve months the different mines lying between Quartz mountain and Carson hill will attract more attention from capitalists and speculators than any other mining section in our State.—Tuolumne Independent.

THE PENRYN QUARRIES.—We paid a hurried visit to the Penryn granite quarries, and were pleased to note the progress that had been made in a short time. A large force of men are engaged in getting out and dressing the stone for the new Stock Exchange building in San Francisco. Massive blocks and pillars of granite cover the ground, and over a hundred men are constantly adding to the amount. The polishing works are in full operation, and the workmen were engaged in setting up several fine monuments that had been just completed. Several fine large pillars for the Exchange building have to be polished, and an immense lathe for this and similar work is now almost ready for use. Altogether, over 150 men are employed about the works, and more are constantly being employed. The presence of such a number of men, all employed in profitable labor, gives Penryn a prosperous air, and as they are all white men, the effect upon business is quite appreciable. Mr. Griffith makes no noise about it, but he is a far more practical opponent to Chinese immigration than many who take occasion to say a great deal. No Chinamen are employed about his extensive works; and this is no spasm of virtue, to work off as soon as the excitement dies away, but has been his uniform practice ever since he opened his quarries.—Placer Argus.

Little York Mining Items.

All the claims in this district that are now being worked, says the Dutch Flat Forum, are owned by the Little York gold washing and water company—an English corporation. H. A. Hagadorn is the superintendent. Generally speaking, the claims so far this season are looking more encouraging than ever before, and the prospects for a good summer's work are flattering.

The Empire claim, located in and adjoining Little York, contains 250 acres of ground, with an average gravel bed of about 70 feet, through which the blue lead channel runs, which, of course, is the richest part of the claim. The claim is worked through a bedrock tunnel 1,440 feet long, which empties into Steep hollow. They use 1,400 inches of water with 235 feet pressure, the water being taken from their own ditch through a pipe 1,000 feet long, which is four and one-half feet at the sand tank, tapering down to 22 inches, and run through two giants with six inch nozzles. Twenty-five white men are employed on this claim (the superintendent does not think it economy to have Chinamen), who are kept constantly employed. This claim has been running since April 1st, and will continue until June 1st before they clean up. Tom Bailey, an experienced and practical miner, is the foreman. An instrument called a deflector is used on the mouth of the nozzle in the claim, which, we think, will prove to be a great labor-saving invention. It is arranged in such a manner that the water from the nozzle moves the giant, and the lever that moves the deflector can be handled by a ten-year-old boy.

The Christmas Hill claim comprises 145 acres of land, with an average gravel-bed of 90 feet. Twenty men are kept at work here. Here they use 800 inches of water, through a pipe 9,000 feet long. They have made four clean-ups this season, every one of which paid a dividend. Mack Eubright is the foreman of the claim.

The Conocil claim, owned by the same company, is run by Chapman & Tibbets. They have made several very satisfactory clean-ups this season. We promised these gentlemen to call over some day and see them, when we may be enabled to get a better idea of what they are doing.

The Liberty Hill claim is also owned by the same company. Here they use 1,400 inches of water, and run right along with a full force of men. From past and present indications it is expected that this claim will prove to be the big bonanza of the Nevada county side of Bear river.

Groom District.

We are sorry to see by the following extract from the Pioche Journal that affairs at Groom district are not progressing favorably:

From William Wescoat, who returned yesterday from Groom district, a mining camp situated about 120 miles southeast from Pioche, and in Lincoln county, we obtain the following particulars concerning that place. The Groom company's mine, the principal one in the district, is at present lying idle, in consequence of an injunction put on the mine by Mr. Osborne, who claims to be sole owner, and that there never was such a corporation as the Groom company. He still holds possession of the mine and mill. Such is the present situation of that camp. There are some dozen miners living in the district, all doing little or nothing. The large saw mill recently erected on Timber mountain by the Groom company, was on last Friday blown down by a heavy gust of wind. The damage done was considerable, and on account of the discouraging state of affairs, nothing will be done towards repairing the wrecked building. Considerable damage was done to the company's mill, and several houses were unroofed and blown down during the storm. Mr. Wescoat thinks the present condition of that section demoralized beyond all redemption, and unless some steps are soon taken to properly arrange the difficulties among the owners and alleged owners of the mines, the place will soon be defunct.

UNIONVILLE ITEMS.—A correspondent of the Silver State writes that a decided change for the better is apparent in Unionville. Times are getting lively and more money in circulation. Everybody who cares to work and is able to do so can find employment. The Arizona mills are in full blast and turning out bullion daily. There is quite a large number of men at work in the Arizona mine, which is producing sufficient ore to run the mills, and some rich enough to ship away. The placer mines south of town furnish employment for a good many men. In Spring canon, Sam Pooley and partner took out last Friday \$64 in dust, and on Saturday the same two cleaned up \$54. In Cottonwood the diggings are looking very favorably. These diggings are far richer and more extensive than the much talked of Black Hills are proving to be, yet it would not be advisable for a great many persons to rush there, as the supply of water is limited.

The ore from the Consolidated Virginia is wet down as it is deposited in the ore house, to save the dust, which is fine chloride of silver and valuable; and in the California mine the ore is sprinkled in the breasts, with the same object. It is made so wet that there is no danger of its being blown away before it reaches the mills.

USEFUL INFORMATION.

Belts, Pulleys and Screws.

The following hints on belts, pulleys and screws contain facts worth remembering: To find where to cut belt holes in floors: Measure the distance in inches from center of driving shaft to under side of floor; on the upper side make a mark over the center of shaft. Now measure the distance from center of shaft on masonry to be driven to floor, making a mark on the floor immediately beneath the center; then measure the distance between the two marks. Transfer these figures to a board or paper, draw off the driving and driven pulleys, after finding their diameters at the distance from each other and the floor line previously obtained, and draw the lines representing the belt cutting the floor line, which will show where the belt passes through the floor. The drawings can be made to a scale to reduce it to convenient dimensions, maintaining the proportions. The holes may now be marked off on the floor and cut with a certainty of being correct. In making the drawing it is best to do it full size on the floor, if room can be had, and allowance must be made for the thickness of the flooring. When a system of pulleys or blocks is operated by a single rope, the charge which can be sustained by the lower block is equal to the weight applied to the end of the rope multiplied with the number of ropes supporting the block. Thus, when the upper and lower blocks possess one pulley each, the load will be supported by a twofold rope; for two pulleys, by a fourfold rope; and, therefore, in the first case every pound on the end of the rope will support two, and in the second case, four pounds on the blocks. The pressure obtained by a screw is found by multiplying the force applied to the lever and twice its length, and with the number 3.1416, and dividing the product by the distance of the screw threads. This rule is founded on the facts, first, that a screw is nothing but a curved inclined plane, of which the circumference is the length, and the distance of the threads the height; and second, that the force is applied by a long lever outside the screw, and moves around the screw at a distance equal to the length of the lever, in a circle to which the diameter is equal to twice the circle or radius, and the circumference equal to twice the radius multiplied by 3.1416. It is also observed here that for every total revolution of the screw it descends as much as the distance of the threads, while the force applied moves through a distance of several feet in the large circle at the end of the lever.

Hints for Practice.

The following compound is said greatly to facilitate the washing of clothes. Dissolve two pounds of bar soap in about three gallons of water as hot as the hand can bear. Add one tablespoonful of turpentine, and three of liquid ammonia. Stir, and steep the clothes in this for three hours, keeping the vessel tightly covered. Then wash the clothes in the usual way. The soap and water may be used a second time, in which case a teaspoonful of turpentine and the same amount of ammonia must be added. This treatment is calculated to save much labor in cleansing summer clothes stained by fruit, etc.

To prepare skins for fur, mix bran and soft water sufficient to cover the skins. Immerse the latter and keep them covered for 24 hours; then remove, wash clean, and carefully scrape off all flesh. To one gallon of water (hot) add one pound of alum and one-fourth pound of salt. When dissolved and cool enough to admit entrance of the hand, immerse the skins for 24 hours, dry in the shade, and rub. Stir the liquor again, immerse the skins for 24 hours, dry, and rub as before, immerse for 24 hours in oatmeal and warm water, partially dry in the shade, and finally rub until entirely dry. This leaves the skin like white leather, and fit for immediate use.

A new and simple blowpipe consists of two large jars connected near the bottom by a piece of rubber tubing. One is filled with water and put on a shelf above the table on which the other stands. The water passes into the latter, and, in doing so, forces the air out through a stopper and piece of tubing into the blowpipe, which is supported separately. With jars of one gallon capacity and an orifice of 0.016 inch, a steady air current of ten minutes' duration is obtained; and to keep it up, one has merely to transpose the jars.

Grease can be removed from billiard or other cloths by a paste of fuller's earth and turpentine. This should be rubbed upon the fabric until the turpentine has evaporated and a white powder remains. The latter can be brushed off, when the grease will have disappeared.

Gold can be applied to glass by mixing it in a powdered state with mucilage and adding a little borax, so that a paste is formed. Having been painted with this compound, the article is heated in an oven. This burns the gum, while the borax vitrifies and so fixes the gold.

A compound of grease and zinc filings is found to be an excellent preventive against rust for iron bolts inserted in wood. It is used to line the bolt hole.

A weak solution of cyanide of potassium cleans gold lace well.

HOW TO CALCEMINE.—Buy the best bleached glue (if dark it is immaterial so the glue is clean), and use it in the proportion of a quarter of a pound to eight pounds of whitening. Soak the glue over night; in the morning pour off the water, as it simply swells while soaking. Add fresh water and put it in a pail, and set that in a kettle of boiling water. When dissolved, stir it into the water, adding enough water to make it, after mixing, of the same consistency as common whitewash. It may be tinted any color, and applied with a whitewash brush. If the color is rubbed smooth in a little water and then mixed with the wash it will be more even. If the walls have been previously whitewashed, scrape away all that will come off, and wash with a solution of white vitriol—two ounces in a pail of water. The vitriol will be decomposed, forming zinc white and plaster of paris, to which calcimine easily adheres. It is important to dissolve the glue in a hot water bath, for if scorched by too great heat its tenacity is impaired or destroyed. Whitening is simply chalk freed from impurities and reduced to a fine powder, and is also known under the name of Paris and Spanish white, though the latter is really a white earth found in Spain. There is a great difference in whitewash brushes, and the beauty of the work, as well as the ease of performing it, depends very much on a good brush, making it well worth while to pay the difference between that and a cheap one. For the inexperienced it is more difficult to lay on tints evenly than pure white.

SPIRITS OF AMMONIA.—"A Farmer's Wife" writes an Eastern journal as follows: There is no telling what a thing will do till you try it. I knew ammonia, diluted in water, could restore rusty silks and clean coat collars, but when I got a green spot on the carpet, I tried half a dozen other things before I thought of that, and that is just what did the work effectively. I put a teaspoonful into about a teacupful of hot water, took a cloth and wet the spot thoroughly, just rubbing it slightly, and the ugly spot was gone. It is splendid for cleaning your silver; it makes things as bright as new without any expenditure of strength; and for looking glasses and windows it is best of all; and one day when I was tired and my dish cloths looked rather gray, I turned a few drops of ammonia into the water and rubbed them out, and I found it acted like a charm, and I shall be sure to do so again some day. I suppose housewives have a perfect right to experiment and see what results they can produce; and if they are not on as large a scale as the farmers try, they are just as important to us, and may make our work lighter and brighter too. Now, I do not believe in luxuriating in a good thing all alone, and I hope all the housekeepers will send and get a ten cent bottle of spirits of ammonia and commence a series of chemical experiments and see what they can accomplish with it. Take the boys' jackets, the girls' dresses, and when you have cleaned everything else, put a few drops in some soft water and wash the little folks' heads, and report progress.

ARTIFICIAL MEERSCHAUM, HORN AND CORAL.—A new way has been found of making excellent imitations of meerscham, horn and coral out of potatoes and carrots. To make the falso meerscham, the potatoes are peeled and macerated for 36 hours in water acidulated with eight per cent. sulphuric acid. They are then dried on blotting paper, and in hot sand under pressure upon plates of chalk or plaster for several days. The chalk supporting the plates must be renewed daily. The resulting material can be readily carved. If greater durability, whiteness and elasticity be desired, the potatoes are macerated in water containing three per cent. of soda instead of the acid above mentioned. To produce the horn imitation, the potatoes, after being treated as last stated, are boiled in water containing 19 per cent. of soda. By substituting carrots for potatoes, a good imitation coral is produced.

WINDOW ORNAMENTATION.—Glass may be made extremely ornamental in several ways, a few of which I will now describe, as perhaps some of our readers may not have heard of them: First cut out various figures from thin white muslin, Swiss, tarlatan, or even tissue paper; stars, circles, rings, diamonds and squares of different sizes are among the best. Make some nice mucilage of gum arabic and paste them on the panes, making narrow lines, connecting them with strips of the material. Arrange all in tasteful designs, and over this give a coat of clear demar varnish.

In the Savage mine the deep foundations for the immense pumping machinery now in course of construction are being laid as fast as the workmen can accomplish the task. The old incline machinery is being removed and new foundations are being laid for the erection of an engine, to be used in hoisting and lowering the pumping machinery in the shaft. Everything is being done that is possible, to complete the improvements now being made at a very early day.

SINKING the new shaft of the Tahoe mine was suspended some days ago, a contract having been entered into between the Tahoe and Lady Bryan for the sinking of a large working shaft on the south line of the Lady Bryan. In consideration for so doing, the Lady Bryan is to have the use of one-third of the shaft, for which they are to pay one-third of the cost. The new shaft has been started.

GOOD HEALTH.

Pulmonary Consumption in Cities.

A tenth of the people of the cities die of consumption. For its prevention, hygienic treatment is the most successful. By drainage the mortality is greatly reduced. An elastic, dry atmosphere is best. Few of the large cities have a mild and equable climate favorable to the respiratory organs, the want of which develops pulmonary complaints. Of the rich, 60 in 1,000 are afflicted with this disease, and 223 to the thousand of the poor. Among the children of the aged and diseased it is more frequently found. When darkness and dampness prevent growth and health, consumption is produced.

The quantity of oxygen is always diminished in cities, even in the streets. Persons predisposed to consumption ought not to be allowed to live in cities. The absence of sunlight is a fruitful cause of the prevalence of the disease. It is not permitted in our houses, and when it does pretend to intrude, our housewives exclude it with heavy curtains. The streets are so narrow and the houses so high that sunlight seldom reaches the sitting-rooms. The school houses are so situated that children can scarcely ever see the sun.

The sun is the source of all light, life and beauty, and is as necessary to give color and health and life to animals as to plants. It corrects musty smells, so prolific of disease. There is no surer way of promoting consumption than by the exclusion of sunlight. Sedentary life and inactivity, impure air and the absence of sunlight in cities produce a fearful mortality from consumption. No exciting cause is so general as in-door occupations.

Excessive dryness, especially in the houses of the rich, is bad for health. Many other influences of city life contribute to its prevalence. Proper food is next in importance to pure air in preventing a development of the disease. To the neglect of supplying to all an abundance of milk and butter is largely attributable the increase and prevalence of the disease. The poor, especially, get but little hydro-carbonaceous food, and with the rich it is not the favorite it ought to be. Close confinement to business, overwork and whatever contributes to impair the vigor of the body tends to develop consumption. The hygienic treatment of all diseases is the great medical fact of the times.

—Professor Frank Donaldson.

Treatment of Burns and Scalds.

At the Graetz medical congress, Dr. Nitzsche, who is surgeon to several factories in Austria, stated that he had noticed that the workmen who met with burns obtain much relief from the application of varnish. This forms a protective covering in the absence of epidermis, and granulation and cicatrization are favored. Dr. Nitzsche thought he could improve upon this, and tried to keep away Pasteur's germs by adding first catholic acid, and subsequently salicylic acid, to the varnish. He considers that he thus succeeded in many cases in effecting prompt healing. These burns were probably in the third degree, with complete loss of epidermis. Another kind of burn, where the epidermis is preserved, but much serum is secreted underneath, has fixed the attention of Dr. Marin, of Geneva. This physician grounds his treatment upon Dutrochet's law of exosmosis, and thinks that the diminution of the serum effused under the epidermis should be obtained without the destruction of the latter. This is effected by the application of thick fruit jellies, say of quince, raspberries, etc. Compresses of lint should be soaked in the jelly, so as to become considerably thickened. The serum transudes into the compress, and when after a day or two it is removed, the epidermis is found shrivelled up, and the parts beneath protected from inflammation and ulceration. Dr. Marin insists upon the rule that when pieces of clothing are adherent to the burned surface, they should not be removed, for fear of dragging the epidermis with them. The compress should be placed on the clothing material, and the exosmosis will eventually go on just as well. Dr. Marin quotes, in a pamphlet on the subject, several cases well calculated to recommend this kind of treatment, concerning which he is very enthusiastic. It is well known that a long time ago jams and syrups were used in France, empirically, in cases of burns. Louis XIV having met with a burn on his hand, his valet de chambre plunged it immediately into a jar of jam with much relief.

HOW WE TAKE COLD.—It is one of the facts best known to science that, when a part of the outer surface of the body has been exposed long to cold, the greatest risk is run in trying suddenly to re-induce warmth. To become thoroughly chilled and then to pass into a very warm atmosphere, such as is found near a fire, results in a dangerous reaction which, a few hours later, may cause pneumonia or bronchitis, or both diseases. The capillaries of the lungs become engorged, and the circulation becomes static, so that there must be a reaction of heat inflammation before recovery can occur. Common colds, says a contemporary, are taken in the same way: the exposed mucous surfaces of the nose and throat are subjected to a chill, then they are subjected to heat; then there follows congestion, reaction of heat, pouring out of fluid matter, and the other local phenomena of catarrh.

THE ECONOMY OF VEGETARIANISM.—A writer in the *Quarterly Journal of Science* makes a trenchant criticism of the arguments usually employed by vegetarians in support of their system of diet. The author considers the question from the economic, the moral and the hygienic points of view, but we have not space to give more than an epitome of his remarks on the first of these topics. One hundred acres of good land, say the vegetarians, will support a greater amount of human life, if planted with wheat, potatoes and other crops directly consumed by man, than if laid out in pasture or set with vegetables intended for the food of cattle. This is true, but all lands are not good; in every country there is abundance of land that is unfit for tillage, and which, nevertheless, yields excellent pasture. Under a vegetarian regime such lands would cease to supply the food market. So, too, the produce of the forest and moor—game—would cease. More serious still, the waters would no longer contribute their share. It might be said that poor lands could still be used for pasture, and the produce of flocks and herds (wool, butter, cheese, milk) utilized. But if the grazier cannot sell the meat, it would be unprofitable to keep animals, unless he could get for the products above named prices a hundred-fold higher than he gets now. Besides, the use of milk, butter and cheese is inconsistent with vegetarian principles. In a strictly vegetarian country, tallow, hides and hair could scarcely be procured. Again, the refuse of the fisheries is rising into importance as a manure fully equal to Peruvian guano. But if fish might no longer be captured, the supply of this fertilizer would be cut off, unless indeed the destruction of animal life for purposes other than food received an exceptional sanction. Even then the cost of raw material would be greatly enhanced.

DOMESTIC ECONOMY.

Nutritive Value of Corn.

Indian corn is one of the most important and healthful articles of human food that a beneficent Providence has bestowed upon man; and to its high nutritive value is due in a large degree the strength and vigor of the race of men who laid the foundation of this great republic. It was much more largely used 50 or 100 years ago than now, as fine wheat flour, for some not well founded reason, has usurped its place in bread making. In the several forms, however, of hulled corn, popped corn, hominy, samp, corn starch, maizeana, etc., vast quantities are consumed by all classes of people.

Meal from Indian corn contains more than four times as much oleaginous matter as wheat flour, more starch, and nearly as much nitrogenous material; consequently in all cold climates it is admirably adapted to sustain the system by furnishing heat-forming compounds. The oil gives warmth, the nitrogenous principle gives muscular strength. The combination of alimentary compounds in Indian corn renders it alone the mixed diet capable of sustaining man under the most extraordinary circumstances. It holds the elementary principles which constitute the basis of organic life. In this particular it is more remarkable than any other vegetable production known to man. There is a large number of dishes of which corn meal forms the basis, which are exceedingly palatable. What, for instance, is more delicious than cold corn pudding out in slices and fried in sweet butter and lard? Hot corn cakes, when properly and skillfully made, are almost invariably regarded as a luxury, and Boston brown bread is famous everywhere in the country. —*Journal of Chemistry.*

Household Hints.

To whiten flannel made yellow by age, dissolve one and a half pounds of white soap in 50 pounds soft water, and also two-thirds of an ounce spirits of ammonia. Immerse the flannel, stir well around for a short time and wash in pure water. When black or navy blue linens are washed soap should not be used. Take instead two potatoes grated into tepid soft water (after having them washed and peeled), into which a teaspoonful of ammonia has been put. Wash the linens in this and rinse them in cold blue water. They will need no starch, and should be dried and ironed on the wrong side. An infusion of hay will keep the natural color in buff linens, and an infusion of bran will do the same for brown linens and prints.

If brooms are wet in boiling sands once a week they will become very tough, will not sweep like a new broom. A handful or so of salt sprinkled on the carpet will carry the dust along with it and make the carpet look bright and clean. A very dusty carpet may be cleaned by setting a pail of cold water out by the door, wet the broom in it, knock it to get off all the drops, sweep a yard or so, then wash the broom as before and sweep again, being careful to shake all the drops off the broom and not sweep far at a time. If done with care it will clean a carpet very nicely; and you will be surprised at the quantity of dirt in the water. The water may need changing once or twice if the carpet is very dirty. Snow sprinkled over a carpet and swept off before it has time to melt and dissolve is also nice for renovating a soiled carpet. Moistened Indian meal is used with good effect by some housekeepers. The broom wears out carpets as much as feet do.

Side Industries of the Salt Mines in Strassfurth, Prussia.

Manufacturing chemistry has never been supplied with such an abundance of crude material as in the salt mines of Strassfurth, in the Prussian province of Saxony. The discovery of enormous amounts of potassa being contained in all the waste and shale of this almost endless deposit of rock salt, caused, soon after the opening of the mines in 1860, an industry to rise which is very little known but nevertheless gigantic and of an incalculable value, namely: the manufacture of potash and salts of potassa.

The masses of rock salt produced are nearly equalled by those of potassa salts gained by a chemical process out of material formerly considered valueless.

The following figures of annual productions will give our readers some idea of the dimensions of this branch of industry:

Chloride of potash (which is worked into potash, sulphate of potash, saltpeter, alum, etc.), 50,000 tons; potash fertilizers of various compositions, 62,000 tons; sulphate of magnesia, 12,500 tons; glauber salts (from mixed solutions of sulphate of magnesia and rock salt), 75,000 tons; chloride of magnesium, 6,500 tons; boracic acid, 20 tons; and bromine, 35 tons.

This great deposit in Germany is equalled by no other in the world except by one in Wieliczka (Hungary), the development of which was unfortunately badly crippled by rash and swindling speculations.

Ventilation of Mines.

No miner can be too much impressed with a sense of the great importance of good ventilation. This air we breathe consists mainly of the two gases oxygen and nitrogen, mingled together in the proportion of about one part oxygen to four parts nitrogen. It is the oxygen which is really necessary for the support of life, whilst the office of the nitrogen is to dilute it and to increase its volume. The air being taken into the lungs in the act of breathing, the oxygen combines with spent carbon from the blood and is thereby converted into carbonic acid, or, as it is sometimes called, carbonic anhydride. Carbonic acid is always injurious when breathed, even if it is mixed with a large volume of pure air, and it should therefore be removed as fast as it is formed. When men work in the open air the carbonic acid formed is very speedily dispersed, and as the supply of pure air is abundant no ill effect follows. But it is otherwise in rooms, and more especially in mines; here the air soon becomes unfit for use if it is not constantly removed, hence the necessity for great care in ventilation. The impurities imparted to the air by the exhalations from the body and lungs are much increased in mines by the constant use of candles or lamps which take away a proportion of the necessary oxygen, and by the explosion of gunpowder or other agents used for blasting. Until within late years comparatively little attention has been paid by companies in this country to the proper ventilation of mines, the miners themselves being the sufferers. Now, however, in the larger mines the question of ventilation is so intimately connected with that of profit that the very best appliances known are used for providing proper ventilation. Winzes are sunk, drifts and connections made, and even costly shafts sunk, simply to give the miners good air so that they may pursue their work with advantage. It is hot enough, usually, below ground, even at the best, and in all cases every care should be taken to see that mines are properly ventilated and cooled.

The miner has always a good test at hand for the fitness of the air he is breathing. If his candle or lamp burns brightly and well the air is fit to breathe, but if he has great difficulty in keeping it alight when the air is still, or if the flame becomes larger and of a pale blue color and flickers greatly or goes out, it is time for him to go out too, as the air which does not support combustion will not support life, and some artificial means of ventilation becomes necessary or the miner's health will give way. This is aside entirely from the question of heat, for the air may be pure and still hot, although perfect ventilation generally assures coolness as well.

Golden State Iron Works.

At these works they now have a number of miscellaneous orders, but they are principally engaged in new and repair work for quicksilver mining companies. They are now making some nine-foot retorts for the Sulphur Bank quicksilver mining company, and have just shipped six condensers to the same company. They have just completed a bench of retorts for the Eureka quicksilver mining company at Ont Hill, Lake county; and also a bench of retorts for the Redington quicksilver mining company. They have made three sets of improved prism pipes for quicksilver furnaces, two sets for the Oceanic and the other for the Ocean View quicksilver mine, San Luis Obispo county. They are putting in several sidewalk hoists in the city, and next week will commence three new elevator hoists. These are after the pattern of Round's patent hydraulic hoists. There are also being made some dump cars for the Great Eastern quicksilver mining company, and several amalgamating pans for the Blue Ledge mine, belonging to an English company. Some work is also being done for the Comanche mine, in Mono county, and for the Indian Queen mine. A large set of hoisting works was shipped from this foundry last month to the Virtue mine in Oregon. The pump wheel was seven feet in diameter, eight inch face.

They are just shipping off two of the Frue concentrators to the Bunker Hill mine, Amador county. In this machine there is an endless belt with raised sides, to which is given a quick lateral motion, and also a slow movement up an incline of from one to twelve inches. A rubber belt is used. The ore is fed on the belt by a spreader. The tailings or lighter portions are carried off at the lower end, through the main box. The quick lateral motion keeps the ore on the belt agitated so as to allow the mineral or heavy parts of the ore to settle through the pulp to the surface of the belt, where it is carried up the incline over the head of the machine, and into a tank of water through which the belt travels, depositing the concentrated material. The capacity of this machine is from seven to eight tons per day, and it is stated that one-half horse power will operate it. We were told when we illustrated this machine in the Press in July, 1875, that there were twenty-four of them in use at Silver Islet, Lake Superior. Those referred to above are the only ones we know yet in use on this coast.

Virginia City and the Comstock Mines.

NUMBER THREE.

[By our Resident Correspondent.]

Having given some account of the Wells-Fargo last week, with a brief mention of this Troy Consolidated, we find next in order the Utah.

This is an old claim, having been located in the year 1859, and is still the farthest north in this district upon which work of any note has been done. It is situated at the head of Seven Mile canon, and at the junction of two smaller ravines, about one mile northwest of the north line of the Ophir. The old company was incorporated under the Nevada law, but in 1871 this was abrogated and a new incorporation had in California. The work done by this old company was west of the location of the present shaft, near the base of Cedar hill. A shaft was sunk about 275 feet and some good ore was taken out. But the new company, considering the dip of the ledge in connection with the angle of the hill, which were about equal, concluded to sink a shaft further east. In this shaft at about 500 feet a troublesome stream of water was encountered, for which the pumping facilities were totally inadequate. After considerable delay a large pumping engine was put up and work was resumed in the shaft, which has now reached a depth of 650 feet, and is still sinking. At 400 feet there is a level, with north, west and south drifts, respectively 400, 700 and 300 feet. Through the west drift connection was made with the old shaft for ventilation.

In the fall of 1875, a few weeks before the disastrous fire in Virginia, the Utah's hoisting works were burnt, at which time all the maps, records, etc., that were kept at the office were destroyed and the machinery much injured. Prompt orders were given for rebuilding, but before timbers could be procured or work commenced the Virginia fire occurred and all lesser interests had to give way to the work of renewal there, and it was not until the completion of the Consolidated Virginia works that a force of workmen could be obtained. The rebuilding is just now completed, and everything presents the appearance of neatness and order. The large pumping engine, one of Booth's, and the double hoisting engine, have been thoroughly repaired and renewed and are working smoothly and well. Fortunately there was not much injury to the shaft, only about four sets of timbers being burned. The most damage was from the water, which nearly filled the shaft and caved in considerable portions of the drifts, which have not yet all been cleaned out. It is found necessary to add another pump, which will be the third, and preparations are now being made for a tank at the present depth of the shaft. Like almost all the mines located on this course, the indications of ore are distinct, and at the 400-foot level the ledge is shown from 75 to 80 feet wide. In this vicinity there are

Many Other Claims,

The most of which are not worked much more than enough to keep alive the title and prevent their relocation. Just opposite and well up the hill is the old Sacramento mine, which in earlier times yielded rich returns from its gold bearing quartz. More recently a mill was erected east of and below the mine for the purpose of working its ores, and a tramway was built to convey the ore to the mill. But at this time the mine is abandoned, the tramway unused and the mill leased out and working on California ore.

Next south of the Utah are several companies that are doing nothing, or a little work by hand, and these are passed for the present. The next in order is the

Phil. Sheridan,

Which is one of the early locations, dating from 1861. Like most of the older companies, their first incorporation was under the Nevada law, which was dissolved and a new company formed under the California law. The first prospecting was done by means of a tunnel, a long one being run well up the side of the hill. Vein matter was reached at a distance of 100 feet and it was continued about 400 feet further, passing through quartz, porphyry, clay carrying gold and ore. The vein was found inclining very decidedly to the east, and it was determined to move several hundred feet down the hill and work through a shaft. In July, 1874, the shaft had reached a depth of 180 feet and a drift of 80 feet had been run towards the ledge, cutting a small body of vein matter on its way and having every indication of approaching the ledge which was cut in the tunnel. After the suspension of the Bank of California work stopped and has only recently been resumed. Now it is being vigorously prosecuted. A new building has just been completed over the hoisting works and the water is nearly all out of the shaft. It is intended to sink the shaft to a depth of 400 feet, before running another drift. The engine has sufficient capacity for depth of 1,500 to 1,800 feet.

There are

No Unusual Developments

To note for the past week. Though the average and every day work of the mines would be

remarkable anywhere else, here nothing less than the discovery of a new and rich body of ore, the millions in which could be calculated, would make a ripple. This hulsion producing mines are confidently expected to come up to their standard and they do not disappoint, the shipments being fully sustained. The product would be much larger if the milling capacity was greater, and that is about to be increased by the erection of an eighty stamp mill by the California company. Others are also projected and it is said that the Consolidated Virginia will rebuild their large mill which was burned last fall. The companies that have not yet reached paying ore and are still prospecting, seem to be fully as active as those that are turning out bullion. A visit along the whole line from the Utah, north, to some distance below Silver City during the past week convinces me that there is a general feeling of encouragement and belief in the future which has hardly ever been exceeded. Improved machinery and appliances contribute largely to this result. Hereafter, when some powerful pumps and other machinery now being put up is completed, it is proposed to give your readers a detailed description of their structure and working. From the great amount of building that is going on everywhere, the town still presents a very unfinished appearance. Building material is scattered promiscuously on streets and sidewalks to such an extent that careful engineering is needed to get through or by, and for the past week the difficulties have been increased on O street by the laying down of new water mains. The water company is providing for an increased supply, intended to meet any future demands. An account of this company's operations is also reserved for a future letter.

Virginia, Nevada, May 16th.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

POSTOFFICE LETTER BOXES.—Elisha T. Barlow, S. F. This invention relates to letter boxes, such as are used in postoffice deliveries, and its object is to provide a convenient means for removing letters from the box. In the ordinary construction of such letter boxes it is necessary for the interior of the box to be large enough to admit the hand and arm of the person who removes the letters. The improvement consists in providing each letter box with a sliding bottom or a sliding bottom with slides which can be drawn out like a drawer for the purpose of taking out the letters in the box so that they can be removed without placing the hand inside the box, thus permitting a smaller sized box to be used. The letters deposited in the box through the rear end will be received by the drawer and when the drawer is pulled out the contents can be readily removed, when the drawer is pushed back and the door closed and locked in the usual way. This economizes space and a much smaller space can be made to answer the same purpose, while it is at the same time more convenient.

IMPROVED KITCHEN TABLE.—Chas. Townsend, Oakland. The object of this invention is to provide an improved table for kitchen use, which will not only be provided with drawers for containing flour and small articles used in cooking, but will also have a sliding board board which can be drawn out upon either side of the table. When the kneading board is closed into the table it is entirely out of the way, and when it is required it is within convenient reach, it being only necessary to draw it out like a drawer. The kneading board will be very convenient in case the table is used as a dining table, as it will serve as an extension for certain articles usually placed on a side board. We illustrated this invention in a recent issue of the Press.

BREECH LOADING ORDNANCE.—J. R. V. Owen, Hamilton, Nev. Mr. Owen's invention relates to an improved arrangement or device for loading cannons of all kinds and it consists of a peculiar interior configuration of the breech of the gun, together with a breech key so shaped as to enter the breech by a direct movement from the rear, and then, by a quarter turn, close and lock the same securely. This is an important invention which we shall shortly describe in detail with appropriate engravings.

THE railroad tunnel at Tomales is completed, and Mr. Wood, the contractor, has moved his camp to the vicinity of Valley Ford. A large force is employed and grading is going on for several miles north of Tomales. The distance from that place to Valley Ford by the line of the railroad is six and a half miles, and to Freestone, ten miles. To the latter place it is expected the road will be in running order early in July.

RICH ore is reported as having been struck in the Paymaster mine, Peavine district. The body is eight feet in width, and is the freest milling ore yet produced by the mine. Ore enough is in sight to run the mill one year.

THERE is intended to be a grand jollification at Nevada City on Saturday, connected with the ceremony of driving the last spike in the Nevada County narrow-gauge railroad.

Philadelphia Machinery Manufactories.

The vast creative and beneficent aids to the development of manufactures, the facilitation of extraordinary accomplishments, the ingenuity and complex arrangements of certain proportionate parts, the wonderful performance of machinery, is more the result of intelligence of the last quarter of a century than ever dreamt or thought of in the slow times antedating that period. The distinction between the periods named is most strikingly seen in the new and various appliances for the performance of every species of labor, and the surprisingly fine work, the wonderful ingenuity which has been brought to bear and make capable the accomplishment of any difficult undertaking, with the essential characteristics of cheapness, increased productive qualities and less manual occupation. Many instances might be adduced as a test of the comparative advance of machinery of one year over another, this condition of affairs materially aided through efforts to devise new processes or mechanical arrangement in order to perform new work, the object being to adapt such mechanical arrangement of parts to the accomplishment of a certain desired result.

Much of original ingenuity in the way of difficult machinery can be directly traced to individuals in small towns as well as those in large cities, and to mechanics whose practical knowledge far outstrips all theoretical acquirements. Many of the hard working, greasy, indifferently-clad machinists, so conspicuous in our machine shops, are the originators, and from whose studious minds were born such mechanical contrivances as are worthy the offspring of gods. It is not the demonstrators of mechanics in any or all its branches who come before us as inventors, but the proficient practical operator and experimenter, the studious, careful and diligent workman—the mechanic. Among the

Successful Inventors and Manufacturers

Of our chief cities, the Meers, Chambers, Bro. & Co., of Philadelphia, are eminently conspicuous, the fame of their establishment being world-wide, and notable as the only similar one in the United States, the several descriptions of machines made not only vying in every particular with those made abroad, but in many important parts superior to similar machines of European construction. And this laudable result is due to the enterprising spirit and advanced intellectual acumen of two brothers, whose original pursuits were in no manner connected with mechanics or any of its essential concomitants. We refer to the brothers Edwin and Cyrus Chambers, manufacturers of book and newspaper folding machines, brick machines, bolt and pivot clippers, etc. The former, now deceased, early allied himself to his brother's fortunes, and through a course of many years, labor, capital and vast profundity of knowledge of mechanism have been called into requisition for the proper construction of the machines, and to have them arrive at a point of superiority hitherto unattained. The entire duties of the establishment now rest upon the shoulders of Mr. Cyrus Chambers, Jr.

Philadelphia and its vast manufacturing and inventive talent can exhibit no greater instance of remarkable powers than have been clearly evinced in the career of this gentleman. Early endowed with a love for mechanical invention, and possessing the indomitable spirit essential to the accomplishment of any great undertaking, he began the series of trials, inventions, undertakings, which led to the grand results achieved and which place him in the foremost list of inventors in this country or the world. It would be a somewhat difficult task on our part to trace from the fountain head the machines we have named, and more particularly the book and newspaper folding machine, or give even a brief mention of the innumerable trials, disappointments and partial glimpses of renown on the part of Mr. Cyrus Chambers, Jr. on his road to success.

It will suffice when we inform our readers that the manufacturing establishment of Chambers, Brother & Co., situated on Fifty-second street, below Lancaster avenue, Philadelphia, is comprised in three acres of ground—the building and adjoining property. Here at all times is presented a busy scene of activity, and from here the machines go out to all parts of the world.

Foremost in the list of manufactures, as regards invention and construction, stands the unrivaled

Book and Newspaper Folding Machine,

The emanation of 20 years' study and labor. The finest books are folded by them with accuracy, speed and economy. A corroborative of their superior claims, it remains for us to remark that all the large book and newspaper publishing houses in the East employ them, as well as establishments as far west as the Pacific slope.

That these machines must necessarily come into greater prominence in California, it is useless for us to argue. Their now extended use in European countries, and the commendations bestowed upon their inventor, Cyrus Chambers, Jr., afford evidence of their superiority over all similar contrivances. The book folding machines will fold an 8vo at about one-fourth, and a double 12mo at one-sixth of the cost of

doing the same work by hand. The newspaper folding machines have now become pretty generally adopted throughout the country. The folding and pasting machines and the folding, pasting and covering machines do work that has not heretofore been done at all, and will fold, paste and cover 8, 16, 24 or 32-page pamphlet at about one-eighth the cost of hand folding, the machines being admirably adapted for binding periodicals, almanacs, etc. Chambers' embossing press, Chambers' automatic feeding board-enter, are unique in their construction and the amount of work which they do.

One of the early successes of this house is the brick-making machine, which is said to be the most perfect working machine of the kind in the United States.

The Bolt and Rivet Clipper.

Is manufactured in three sizes, ranging in price from \$7.50 and \$9 to \$12, is a little device for cutting off the ends of bolts and rivets, on carriages, wagons, harness, etc., also core rods in foundries, etc., and is the best instrument of the kind ever devised. They are used generally by carriage makers, the wheelwright, blacksmith, and wherever bolts and rivets are used.

It must not be thought that the wonderful instruments and devices of this establishment of which we treat are the emanations of a short

TABER'S IMPROVED HAY FORK.

period of time. Indeed, they are the result of many years of labor, advanced knowledge of mechanics, and expenditure of capital. To the surviving brother of the firm we are indebted for the successful accomplishment of the machines and their now extended use throughout the world. The machines named will be exhibited at the Centennial exhibition and their practical importance demonstrated to thousands of people of every nation and clime. H.

IMPROVED BELT HOOK.—We illustrate on this page Sherman's patent double-hitch belt hook, which is being introduced on this coast by

DOUBLE HITCH BELT HOOK.

T. L. Bailey, of Batavia, Solano county. This hook retains its original shape in the belt, and can be used until worn out. It is an excellent substitute for lace leather. The cut conveys a correct idea of the manner of adjusting these hooks. It will be observed that the substantial double bearing of each hook precludes the possibility of "tearing out."

JUNGES AT THE CENTENNIAL.—Among the American judges who are to pass upon the articles at the Centennial, are the following: On mines and metallurgy—S. B. Axtell, of New Mexico; J. W. Mackey, of Nevada; J. D. Hagne, of California; W. S. Keyes, of Nevada. On animal and vegetable products—General H. M. Naglee, of California. On furniture, upholstery, etc.—General Gibbons, of Montana. Wool and silk fabrics—H. C. Goodspeed, of Utah. Jewellery, silverware, bronze, etc.—Peter Gottschell, of California. Machines, tools, wood, metal and stoves—Irrving M. Scott. Machinery for making clothing and lace—L. B. T. Poor, of Dakota. Agricultural implements—James Bruce, of Oregon.

NEW TUNNEL.—The Eberhardt and Aurora silver mining company at White Pine broke ground for their new tunnel on the 12th inst. commencing in Mahogany canon, cutting the Eberhardt and South Aurora mines in its course. Burleigh drills and other modern appliances will be used to hasten the work.

The first car between Colfax and Nevada City is to be fitted up elegantly by the ladies of the town last mentioned.

Taber's Improved Hay Fork.

We give illustrations on this page of an improved horse hay fork recently patented by Orrin Taber, of San Jose, through Dewey & Co's agency. This useful farm implement has in the short time since it was put into work secured more than the usual amount of approval from those who have given it full trial. We have seen most favorable testimonials of its excellent and efficient work. Mr. Taber's improvement over other hay forks of similar model lies in ingenious mechanical devices for operating the two sets of fingers, by which the requisite amount of strength together with positive action of the grasping and releasing fingers are secured. The heads of the two sets of fingers are joined in the opposite ends of two end plates, and these end plates are connected together between the heads by means of rods or bars which extend across parallel with the heads, thus providing a spacing frame for separating the heads and permitting the points of the fingers to describe a larger curve when they open and close than if the heads were closer together, consequently causing them to enter the body of hay with greater ease. This improvement is a very val-

TABER'S IMPROVED HAY FORK.

uable feature of the fork and its result in working is readily perceived.

The great value in the patent, however, lies in the arrangement for holding the load and for releasing it when the place of deposit is reached. This work is wholly automatic and consequently very important as a labor saving feature. The arrangement is such that when the load is gripped the weight of the fork and its load are suspended from a lifting bar, and as this lifting bar is attached to crank arms which act upon the fingers or teeth, the pull upon it closes the fork. When the fork has been lifted to the point where the load is to be deposited, a light pull upon a rope which is

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANES.]

(Continued from last week.)

B.—Sapphire, Asteria or Star Sapphire, Oriental Amethyst, O. Emerald, O. Ruby, O. Topaz.

The above are names given to varieties of the same mineral which is properly corundum crystallized, the main difference being color, although it will be shown that the specific gravity of varieties differs. The name sapphire generally refers to the blue or white variety. A red sapphire is a ruby, a yellow one a topaz, and the green is an emerald. The word oriental prefixed shows that they differ from other stones of the same name, but of inferior quality. They are so called because the best stones come from India. Corundum takes its name from a Hindoo word, *korund*. The name generally applies to the opaque and massive varieties. Emery is a coarse, impure variety, which is well known as a polishing material. Its color is black or grayish black color. It is an intimate mixture of corundum with hematite or magnetite; much resembles a fine grained iron ore.

Corundum is found in several forms. Adamantine spar from India is black, dark gray or smoky tint, sometimes crystallized, but generally massive. It has no value except for polishing purposes, being in fact a pure emery. Emery occurs in several localities in the United States: in Massachusetts, New York, Maine, Connecticut, New Jersey, Pennsylvania, North Carolina and in Canada. The only known locality in California is Los Angeles county, in the drift of San Francisco pass, where it has been observed in small quantities.

It is found largely in Asia Minor, near Ephesus. It occurs also in China, and, in fact, is quite common in small quantities in different parts of the world. Although the coarser kinds are so common, yet the crystallized varieties are extremely rare, and are second only in beauty and value to the diamond.

The white sapphire is almost equal to the diamond as a gem, and is nearly as hard. It has a specific gravity of 3.95-4.16; hardness, 9. Its composition is pure alumina (Al₂O₃) oxygen 46.6, aluminum 53.4=100. Before the blowpipe it is unaltered. With borax the pulverized mineral dissolves slowly when strongly heated, yielding a colorless glass. It is not acted on by acids; acids do not attack it. The finely pulverized mineral, if wet with a solution of proto-nitrate of cobalt and strongly heated becomes blue, which is the well known reaction of alumina. If fused with bi-sulphate of potassa it becomes decomposed and dissolves in water, from which the alumina may be precipitated by ammonia.

The sapphire in any of its varieties is electrical when rubbed, by which it may be distinguished from other similar stones which are not.

Sapphires are found in the sand of some rivers associated with zircon garnets, magnetites, chromite iron and other minerals, and in basalt. The luster of the sapphire is adamantine or vitreous; fracture conchoidal, uneven.

The specific gravity of the different varieties is as follows: blue, 3.979; red, 3.909; green, 3.949; violet, 3.921.

(To be Continued.)

Heat and Mechanical Force.

EDITORS PRESS:—In your issue of March 25th, your correspondent "Observer" propounds some questions upon heat and mechanical force, as applied to an ordinary non-condensing steam engine, at 60 pounds pressure. It would seem to me that the unit of heat, applied as above, would exert a mechanical force which would raise one pound only about sixty feet high. In a steam cylinder, cut off at one-fourth the stroke, the unit of heat would raise one pound about 120 feet high. Cut off at one-twelfth the stroke with steam at 150 pounds pressure to the square inch, the same equivalent of heat would raise one pound 240 feet high.

Making fair allowance for loss of heat, it would require about four pounds of the best anthracite coal in the first case stated, two pounds in the second, and one pound in the third per hour, to produce one practical horse power.

A good condenser would save, or economize the above statements, both as to fuel and power, say 15 percent.

These are the best results we shall probably ever obtain from the most perfect steam engine.

If it were possible to confine a given quantity of water at boiling point in a cylinder and impart to it about 1,000 additional units of heat to each pound of water, then allow it to expand against the piston throughout 1,600 times its volume and add together its expansive force exerted at all points in length of the cylinder, and divide by the total number of points, you will have a force about equal to Joule's equivalent.

STEAM.

San Francisco, May 15th, 1875.

A great celebration and reunion of old residents of Nevada county will take place at Nevada City on the 26th inst.

AGENTS.—Mr. C. N. West will act as agent and correspondent for us in Santa Cruz county, and Mr. F. A. Schofield, at Santa Rosa and vicinity.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS ON THE LEGS OF TRIPOD, ARE ALL IMPROVED AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never fails of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

THE EXPLORERS', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price, cloth, 10.50; in leather, \$12; postage 50 cts. Sold at this office.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur at any time, please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: 4 76; or 4/176.

THOUGHTLESSNESS.—Persons sometimes return the paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

SMITH'S PATENT POWER MORTISERS,

Mortiser.

WITH LATE IMPORTANT IMPROVEMENTS.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

(Continued from page 328.)

Arizona.

PROX DISTRICT.—Arizona Miner, May 5: Houghton & Orrin have let a contract to some parties who are sinking on the Prince. At the Black Warrior evidence of active operations was visible in healthy looking dumps of fine looking ore. Monk & Co., who have a lease on the Evening Star, were preparing a slide, buckets, etc., and getting ready to commence sinking. Mr. Coe was clearing away a place at the mouth of the McKinnon & Goodwin tunnel to sink a shaft some 200 feet as preliminary to further operations.

Rod McKinnon was sinking and doing assessment work on an intervening claim between the mine they sold to Coe and the Jackson or War Eagle claim, on the same ledge. All these mines will receive attention as they are developed.

Idaho.

ORO FRO.—Owyhee Avalanche, May 6: Orders came from San Francisco a few days ago to parties here directing them to resume paying off claims against this mine. The indebtedness is being gradually reduced, and it is believed that matters will soon be in shape to pave the way for the resumption of work in the mine. We hope so.

THE GOLDEN CHAMBER.—We continue to receive the most favorable reports of the condition and prospects of this mine. Superintendent Baldwin assures that all the recent developments continue to be most favorable, and that there is every prospect of reaching the promised bonanza at the 13th level. Shares have been recently selling at \$4 and upwards.

The great majority of the workmen in this camp have come up nobly in the way of surrendering their claims against the mine, with a view of throwing aside all obstacles in the way of resuming work. All honor to them for their manly course in making such sacrifices.

SOUTH MOUNTAIN.—Mr. Bowyer, Secretary of the South Mountain Consolidated mining company, arrived here yesterday from South Mountain. We are pleased to learn from him that the indications are very favorable for the resumption of mining operations in that camp early in summer. Some of the small lien holders are disposed to be dissatisfied at the course matters have taken, but it is earnestly hoped that they will see the propriety of compromising and getting what they can, so as to leave no obstacle in the way of resumption. When the works are started all concerned will be benefited.

LEWIS C. GROVER.....President.
JAMES B. PEARSON.....Vice-President.

EDWARD A. STRONG.....SECRETARY.
BENJ. C. MILLER.....TREASURER.
B. J. MILLER.....ACTUARY.

The following is a summary of the business of this company from May 1, 1845:

Total Receipts.....	\$81,149,507 76
Paid Losses and Endowments.....	19,284,641 48
Dividends or Return Premiums.....	19,224,524 15
Surrendered Policies.....	4,284,344 82
Expenses—Management, Commissions, Taxes, etc.....	8,167,913 05
Ratio of expenses.....	5.60 per cent.

These results are more favorable to the insured than those presented by any company in the world.

ALL KINDS OF APPROVED POLICIES ISSUED.

Dividends paid annually, or they can be applied on the Accelerative Endowment Plan, ORIGINATED BY THIS COMPANY, to which particular attention is called.

ACCELERATIVE ENDOWMENT PLAN.

The plan is intended to meet the wants of those who wish protection for their dependents in case of premature death, and at the same time to make a wise provision for themselves in the event of surviving the productive period of life.

The plan proposes that instead of using dividends in reduction of the annual premium, the insured may, at his discretion, pay his premiums in full in cash, and surrender his dividend to the company. In consideration of this surrender, the company will agree to pay the sum assured when the policy-holder shall have attained a certain age, or at his previous death, instead of at death only, thus enabling him to procure an Endowment Policy at the usual rates charged for policies payable at death only.

If the policy is already an endowment, payable at a given age or previous death, the surrender of the dividend will enable the company to agree to pay the policy at a still younger age.

The Mutual Benefit Life Insurance Company issues Policies insuring the lives of healthy persons residing in any part of the United States.

Mining and Other Companies.

Persons interested in incorporated shares
will do well to recommend the publication
of the official notices of their companies
in this paper, as the cheapest appropriate
medium for the same.

Amador Canal and Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Jackson, Amador County, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the ninth day of May, A. D., 1876, an assessment, No. 1, of three dollars (\$3.00) per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at 134 office of the company, room No. 2, 418 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the 15th day of June, 1876, will be delinquent, and
advertised for sale at public auction, and unless payment
is made before, will be sold on Wednesday, the fifth day
of July, 1876, to pay the delinquent assessment, together
with costs of advertising and expenses of sale. By order of
the Board of Directors. J. W. CLARK, Secretary.
Office, Room No. 2, 418 California street, San Fran-
cisco, Cal.

Hope Quicksilver Mining Company.—Lo-

cation of principal place of business, San Francisco, Cal. Location of works, Cannabar Mining District, Sonoma County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 12th day of May, 1876, an assessment (No. 1) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room No. 2, 408 California street, San Francisco, California.

Any stock upon which this assessment shall remain un-
paid on the 15th day of June 1876, will be delinquent, and
advertised for sale at public auction, and unless payment
is made before, will be sold on Monday, the 10th day of
July, 1876, to pay the delinquent assessment, together with
costs of advertising and expenses of sale.

JACOB HARRY, Secretary.
Office, Room 2, No. 408 California street, San Francisco,
Cal.

Lady Franklin Gold and Silver Mining Co.

Location of principal place of business, 507 Mont-
gomery street, San Francisco, Cal. Location of works,
Silver Mountain Mining District, Alpine County
California.

Notice.—There are delinquent upon the following
described stock, on account of assessment, (No. 14)
levied on the third day of April, 1876, the several amounts
set opposite the names of the respective shareholders,
as follows:

Names.	No. Certificate.	No. Shares.	Amount.
James Wilson.....	246	5	\$ 2 50
James Wilson.....	250	5	2 50
Donald Davidson.....	136	10	5 00
Donald Davidson.....	137	10	5 00
Donald Davidson.....	193	5	2 50
Donald Davidson.....	257	102 1/2	51 37
Donald Davidson.....	258	13	6 50
T. S. Beaver.....	106	10	5 00
T. S. Beaver.....	287	10	5 00
Alexander Martin.....	266	100	50 00
Alexander Martin.....	267	100	50 00
Alexander Martin.....	218	8 1/2	41 25
Alexander Martin.....	283	30	15 00

And in accordance with law, and an order of the
Board of Directors, made on the third day of April,
1876, so many shares of each parcel of said stock as
may be necessary, will be sold at public auction, at the
office of the Company, 507 Montgomery street,
San Francisco, California, on Monday, the 30th day
of June, 1876, at the hour of one o'clock, P. M., of said
day, to pay said delinquent assessments thereon, to-
gether with costs of advertising and expenses of the
sale.

F. E. LUTY, Secretary.

Office, 507 Montgomery street, San Francisco, Cal.

Mariposa Land and Mining Company

of California. Location of principal place of business,
San Francisco, Cal. Location of works, Mariposa
county, Cal.

Notice is hereby given, that at a meeting of the Board of
Directors, held on the second day of May, 1876, an assess-
ment (No. 5) of one dollar per share was levied upon the
capital stock of the corporation, payable immediately in
United States currency, to the Secretary, at the office of
the company, No. 309 Montgomery street, room 33, Nevada
Block, San Francisco, Cal., or to the Assistant Secretary,
at the office, No. 3 Nassau street, New York.

Any stock upon which this assessment shall remain un-
paid on the third day of June, 1876, will be delinquent, and
advertised for sale at public auction, and unless payment
is made before, will be sold on Friday, the 30th day of
June, 1876, to pay the delinquent assessment, together with
costs of advertising and expenses of sale. By order of the
Board of Directors. LEANDER LEAVITT, Secretary.
Office, Room 33 Nevada Block, No. 309 Montgomery
street, San Francisco, Cal.

Walter Mill and Mining Company.—Prin-

cipal place of business, City and County of San Fran-
cisco, Cal. Location of works, Garden Valley Mining
District.

Notice is hereby given that at a meeting of the Board of
Directors, held on the fifteenth day of May, 1876, an assess-
ment of twenty (20) cents per share was levied upon the
capital stock of the corporation, payable immediately in
United States gold and silver coin, to the Secretary at
his office, 601 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain un-
paid on the twenty-first day of June, 1876, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Thursday, the sixth
day of July, 1876, to pay the delinquent assessment, to-
gether with costs of advertising and expenses of sale.

SAMUEL S. MURPHY, Secretary.

Office, 601 Montgomery street, San Francisco, Cal.

Schofield's SULPHURET CONCENTRATOR.

THE BEST MACHINE IN USE FOR
SAVING SULPHURETS.No Power Required to Run it, and only a Small Stream of
Water under a Light Pressure.

ECONOMICAL,

EFFECTIVE,

DURABLE,

AND SURE IN OPERATION.

The especial attention of parties erecting new mills is called to this
Valuable Improvement.WE GUARANTEE THAT THIS MACHINE WILL SAVE NINETY PER CENT. OF ALL THE SULPHURETS
IN THE ROCK AT A MERELY NOMINAL EXPENSE. IT HAS NOW STOOD THE SEVERE
PRACTICAL TESTS OF OVER A YEAR'S WORK AT DIFFERENT MILLS
ON THIS COAST, AND HAS BEEN EMINENTLY
SUCCESSFUL IN EVERY CASE.The following letters, from practical men who have used this machine, will show to
those interested what it has accomplished:

BANDERETA MINE,

Mariposa County, Feb. 7th, 1876.

CHAS. SCHOFIELD, Esq.—Dear Sir: We have been using your Concentrator at our mill about six months, and find that it saves over 90 per cent. of the sulphurets contained in the ore, and all of the amalgam and quicksilver which escapes from the battery. The machine is simple in construction, perfect in operation, and requiring no power to run it, is very economical. I can confidently recommend it to all mill men as the best and cheapest Ore Concentrator now in use.
Yours respectfully, LEVI NOBBS, Superintendent.

NONPAREIL GOLD MINING CO.'S WORKS,

Deer Flat, Tuolumne County, Cal., April 12th, 1876.

MR. CHARLES SCHOFIELD—Dear Sir: It is four months since the Sulphuret Concentrator you furnished our company's mill with was first put in operation, and during the past three months has been clearly in constant use. The men attending the Concentrator having acquired by practice a thorough knowledge of its workings, there is nothing more to be desired; it is perfect. A number of mill men have examined the Concentrator and its workings, and pronounce it the most simple in its construction, perfect in its work, and cheaply run of any they had seen. If you think by showing this it will assist you in disposing of your Sulphuret Concentrators, you are at liberty so to do, as it will afford me much pleasure in having contributed my little mite towards rewarding true merit. Hoping you will meet with complete success,
I remain yours truly, JOS. J. DuPRAT, Superintendent.

CON. ALABAMA M. CO.,

Tuolumne County, May 1st, 1876.

C. SCHOFIELD, Esq.—Dear Sir: The Concentrating Machine recently purchased of you is now in active operation, and we are highly pleased with it. It saves over 90 per cent. of our sulphurets, and is run with very little expense. We could not afford to be without it, and can safely recommend it to all mill men as the best and most economical machine in use.

M. S. McCONNELL, Superintendent.

WASHINGTON MINE,

Mariposa County, Cal.

CHAS. SCHOFIELD, Esq.—Dear Sir: Having had one of your Double Rigged Concentrators in use now at this Mill for over a year, I take this opportunity of informing you that it is far superior to the old English Boddie we have been using for the last four years, not only in a saving of labor, but having a less waste of sulphurets in washing.

We have the machine connected with the tail sluice, and receives the sand and water direct from the batteries, without any hoisting, and it does the concentration for the 20 stamps easy, with a loss of less than 10 per cent.

Two Chinamen do all the work required—one night and the other day—working 12 hours each, and get out about a ton each day, thus concentrating 30 tons into one, at a cost of less than four dollars. As the cheapest, most economical and best working Concentrator I know of I can recommend it to others without any hesitation.

Yours truly,

GEO. E. WEBBER, Jr.,

Superintendent Washington Mining Company.

MR. SCHOFIELD—Dear Sir: Having carefully examined your Concentrator, which I have seen in successful operation at the Francis Company's Mill and also at the Benton Mills, on the Mariposa Estate. I have no hesitation in saying that it is the most valuable Concentrator I have met with during my long experience as an amalgamator in this country. Its manner of catching quicksilver and amalgam is thorough and complete, and it saves the sulphurets clean and with a loss of less than ten per cent.

Yours respectfully,

L. BURDOW.

MR. C. SCHOFIELD—Sir: I have worked one of your Sulphuret Machines at the Benton Mills about 30 days, and am satisfied it is the best machine for saving amalgam and sulphurets ever used on the Mariposa Estate.

L. GILMAN.

The following testimonial is from the well known mining expert, PROF. J. E. CLAYTON:

CHAS. SCHOFIELD, Esq.—Dear Sir: Having followed the business of mining engineering for upwards of 30 years, and having had in this connection much to do with regulating machinery for saving gold and concentrating sulphurets, and having in nearly every mining camp on the Pacific Coast examined the various kinds of Ore Concentrators in use, I will say that I have nowhere seen anything half as cheap and simple in its construction, scientific in principle or effective in operation as your machine.

J. E. CLAYTON.

Machines can be Furnished at Short Notice. In all Cases we Furnish the
Concentrator Complete, Set it Up, and Instruct the Buyers as to
the Proper Way of Managing It.

LATEST IMPROVED
HENDY & COCHRANE'S ORE FEEDER
FOR QUARTZ MILLS.

AWARDED FIRST PREMIUM AT THE 10TH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Mr. Lachman, of the Southey Mill, Tuolumne County, says they work splendidly; could he have better. Two of the machines were shipped to the California Company, Nevada City. C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine." S. D. B. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success. C. C. Hewitt, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

SACRAMENTO, May 29th, 1875.

Messrs. Dewey & Co., Gentlemen:

Yours of the 27th inst. is received. The patent came duly to hand yesterday, by express. Please accept thanks for your promptness in obtaining the same. Very respectfully,

DUNCAN BEAUMONT.

PASO ROBLES, CAL., October 18th, 1875.

Dewey & Co., Gents: The letters patent for the Tire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks.

Yours Respectfully, JOHN H. MERTZ.

HERCULES POWDER.

HERCULES Slaying the Giants.

[Hercules, the son of Jupiter and Alcmena, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Enrythens to execute a very great task, when he found himself opposed by several Giants, among whom were the powerful Giant Geryon, Enrytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.
2. **UNIFORMITY.**—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.
3. **SAFETY.**—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.
4. **CARTRIDGES.**—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.
5. **ECONOMY.**—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. {Hercules X X No. 1, for extreme hard rock.
Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself*:

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D., 1875.

Present:—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.
THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, Et AL., *In Equity*, No. 1,233.—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., Solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered herein dismissing said bill.
Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

Patent Solicitors.

SAN FRANCISCO, SATURDAY, MAY 27, 1876.

VOLUME XXXII
Number 22.

A Favorable Report.

It is with satisfaction that we lay before the readers of the PRESS the report of Mr. Knox, who was sent out by the Advance silver mining company for the purpose of giving their mine a thorough examination. Mr. Knox, after submitting the mine to a thorough inspection, reports as follows:

To the Directors of the Advance silver mining company.—Gents: At your request I visited and carefully examined the mine belonging to your company, on Monitor mountain, Alpine county, California.

I found on the property about 900 feet of tunnels, three or four short cross-drifts and two shafts. Shaft No. 1 is the working shaft. It was, when I was there (April 26th 1876), 195 feet deep, and entirely in hanging wall rock (propylite.) Shaft No. 2 is near the extreme west end of the tunnel, on what is called the foot wall, and is about 150 feet deep. The last 70 feet in depth of this shaft contains excellent concentrated ore—black sulphurets of silver, with traces of zinc blend and copper. This shaft is about 550 feet northwesterly from the working shaft, and the pay chute about 15 feet thick, solid.

I am confident that the true west wall of the vein has not yet been reached by the northwesterly drift, but as far as developed the vein is over 400 feet thick. The concentrated ledge or the hanging wall, as prospected by the drill, is at least 30 feet thick of excellent milling ore. The hanging wall, immediately in contact with the east vein, is a porphyritic quartzose rock, or propylite of considerable thickness, backed up by a solid formation of blue trap rock, of over two miles in thickness. The west or foot wall is supported by the same material as far as explored, and this by blue trap extending far to the west. I could not tell how far, the snow in that direction covering the mountains. The opening in the trap rock through which the vein protrudes, extends in a northerly and southerly direction for at least 12 miles. The "blossom" or outthrow from the vein is enormous, extending some two miles in length and nearly one mile in width. It has never been my fortune to see anything that compares with it in magnitude.

This outcrop is of no practical value, but demonstrates the great size and strength of the vein. The vein has never been explored to any depth, where it might be expected to become solid in its formation, but this is being done as rapidly as possible by the working shaft. At the depth of three hundred feet, the shaft will cut the east wall of the east vein, from which good milling ore can at once be extracted.

I should perhaps mention that in the "blossom" from the vein, very rich pockets of ore, principally sulphurets of silver and iron, have been found, varying much in size, some containing a few pounds and some many tons, each pocket entirely isolated from the other, and giving no indication of their position except by actual contact. This goes to show that when the true vein is reached, rich ore will, without doubt, be found in it. Experience in the Comstock lode confirms this opinion. Another point which indicates the early concentration of the vein, is that the outcrop or blossom rises nearly 1,300 feet above the level of the top of the working shaft.

Yours truly,
ISRAEL W. KNOX.

THE "FOURTH" MORE GLORIOUS THAN EVER. It is plainly to be seen that the determination to make the approaching anniversary of the Declaration of American Independence more glorious than ever, is not limited to our own State. From all quarters we hear of these extra notes of preparation, proving that the large portion of American patriotism which was not enabled to attend the Centennial will keep the great holiday in a proper manner at home. In many places arrangements are being made to devote three consecutive days to the celebration. The preparations, so far as we have been informed, are in good taste and the proper spirit is infused into the whole matter. It is safe to at least predict an unusually "Glorious Fourth."

SCHOOL VACATION.—A six weeks' vacation of our public schools commenced on Saturday of this week. The pupils are reconciled.

King's Patent Galley Supporter.

The engraving illustrates the working of a patent designed to save a large amount of time and trouble for printers. The "supporters" are metal castings, forming a straight grooved piece between two parallel pieces, disposed at the ends and at right angles thereto. The groove in the central portion and notches in the cross piece fit over the transverse partitions of the case, and the galley rests against one cross piece while the other presses against the longitudinal partition or edge.

This patent, when placed in position on the lower case, prevents the galley from covering the lower tier of boxes and the compositor has free access to every box in the case, without having to lift or disturb the galley at all. Without the "supporters" the galley cannot be placed on the case without covering a number of the letter boxes, and must be lifted every time a letter

PAUL'S PATENT AMALGAM SAFE AND MERCURY DISCHARGER.

is required from the boxes so covered, thus necessitating a waste of time and labor that would repay its value daily. Practical printers will readily understand and appreciate the convenience of this invention and profit by the ingenuity of the inventor.

K. S. Johnson, 43 and 45 Powers street, Brooklyn, E. D., New York, has become sole proprietor of this patent. We are informed they are now in daily use in the largest printing establishments in New York city, and are acknowledged to be an indispensable acquisition to the trade. They are retailed at 50 cents per pair, and will save that amount daily to every compositor using them. State and county

KINGS' PATENT GALLEY SUPPORTER. rights to sell or manufacture can be had on application to the proprietor.

COAL AT SANTA ROSA.—A correspondent writes us from Santa Rosa that Mr. C. W. Frost discovered during the past winter "a first class cannel coal mine" in the mountains of the adjoining township, with a vein 12 or more feet wide, and of an unknown depth. A company has been formed, of \$10,000,000 capital, to develop this mine, and also, probably, to run a new railroad in connection with it from Santa Rosa to San Francisco.

The miners who left for the Black hills are returning daily, declaring that the new El Dorado is a fraud, not only as regards gold but in the matter of timber.

Paul's Patent Amalgam Safe and Mercury Discharger.

The accompanying cut exhibits this new device for "cleaning up" pans or settlers and securing amalgam, lately patented through our agency by the well known inventor, Mr. Almarin B. Paul, of this city. It is adapted to all kinds of amalgamating pans or settlers, and can be applied at a very trifling cost. By it all amalgam is absolutely under control of the superintendent, and beyond the inspection of any party not duly authorized.

Explanation of Cut.

A represents pan or settler; Fig. 1 is a bowl on outer edge of settler or pan; Fig. 2 represents a screw, which closes the connection between safe and vessel, when it is desired to take out amalgam; Fig. 3 represents the safe, where amalgam is deposited by gravity; Fig. 4 is a guard, which prevents abstracting

amalgam by any device; Fig. 5 is a pipe with adjustable joint, through which all mercury free of amalgam passes out for re-use; Fig. 6 is a lock, which prevents the opening of the two points of discharge; Fig. 7 is a dial, which is used to regulate the flow of mercury. The whole operation is based on the specific gravity of water, ore, mercury and the precious metals, and is as exact and certain to operate as the law of gravity itself. It will thus be seen that the arrangement is such that the mercury can be retained in the pan or settler as long as desired for amalgamating; and at will the pan or settler, or fifty pans or more, can be practically cleaned up in a few minutes, without stopping machinery. The mercury carries the amalgam to the safe, then passes on, freed of it, to a receiver for re-use. The safe and mercury discharger is one of the appendages to the "Paul Process." There are several of these machines in practical operation, and all give the most complete satisfaction. This cut represents the attachment to a pan. By a very simple change they can be connected to sluices in hydraulic mining, and so be arranged as to not only be a safe, but answer a purpose as a depository of the gold and securing it beyond further danger of washing off. They are made of capacity to hold from \$500 to \$10,000 of gold amalgam.

The time saved in cleaning up pans must make this a valuable addition to our mining machinery, and is one more item to that grand ultimatum of extracting the precious metals without stopping machinery or extra handling of anything. Mr. Paul's address is Room 20, Safe Deposit building, San Francisco.

ANSWERS TO CORRESPONDENTS.—"J. H. S.," Miners' foundry. The specific gravity of water being equal to 1, of course anything will sink in it the specific gravity of which is greater than 1, such as the articles you mention. Wood, although its gravity is in most instances greater than 1, swims, because it is porous, but when these pores become impregnated with water, it will also readily sink. Convince yourself by experiments.

THE State of Oregon has received from the General Government 90,000 acres of public domain for the purpose of establishing an agricultural college.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANKS.]

(Continued from last week.)

B.—Sapphire, Asteria or Star Sapphire, Oriental Amethyst, O. Emerald, O. Ruby, O. Topaz.

The red sapphire is the true oriental ruby, and is the most valuable of all gems; even more so than a diamond of equal weight. The first specimens came to us from Ava in Siam. They are also found in Ceylon. The mines of Burmah are the most productive. The rubies are found by sinking shafts and washing the stratum in which they lie with water. The stratum is of unequal depth, sometimes being found near the surface while at others it is not found until a depth of 30 feet is reached. These mines belong to the Government and no European is allowed to approach them on any condition.

The color of the ruby is not always constant, being found from a bright red to a deep crimson. The peculiar tint known among connoisseurs as pigeon's blood is the most esteemed.

The blue sapphire is the next in value; perfect stones of this color are very rare. It is remarkable that generally the stone is not uniformly blue, and great care is required in cutting it to good advantage. A perfect sapphire should appear the same tint of blue by candle-light as by daylight, which is seldom the case. That peculiar blue, formerly called *bleu du roi*, which resembles the blue of velvet, is the most sought.

The yellow sapphire is called the oriental topaz; when of good color is very valuable; it is brilliant, and is often taken for the yellow diamond. It is usually found of a light straw color, when it is not so highly valued.

The oriental emerald is thought to be the rarest of gems. One of the most eminent jewelers in Europe says that he has never met with but one specimen.

The oriental amethyst is a sapphire which has a purple color. It is far more brilliant than the common amethyst, and is a charming gem which is greatly prized; it may be distinguished from the amethyst by its superior hardness.

Some sapphires show a star when held in a strong light and in certain positions; star sapphire, asteria and oriental glass are different names for this gem.

The sapphire is cut in much the same way as the diamond, and the lapidary has often the opportunity of showing his skill in cutting this gem, to remove the impurities of the blue variety and to display the natural beauty of the asteria improved by his taste and skill.

In setting the sapphire, colored foil is generally placed under the stone to lighten its color, the foil being in every case that which it is desired the stone shall be. The proper use of the foil requires much skill and judgment. The temptation to imitate the sapphire is so great that great care should be taken to ascertain the genuine character of a stone when about to purchase. Not only are other inferior stones, yet to be described, substituted for the sapphire, but a glass or paste imitation is often found in commerce. The hardness test will always detect this counterfeit.

(To be Continued.)

PLATES COATING WITH VERDIORIS.—"Many Miners" desire to be informed concerning the best method for preventing the coating of the copper plates of quartz mills. We would inform them that different mills use different materials. Some use sodium amalgam, which can be bought of any first class druggist, ready prepared for spreading on the plates. This is perfectly harmless. Others prefer cyanide potassium. This also can be had of the druggist ready for spreading on the plates, but it is a deadly poison, and should be so marked, and our friends should be careful what hands they trust it in.

JOINT TARGET EXCURSION.—Company "F," Capt. J. E. Hughes; Company "H," Capt. H. P. Bush, and Company "D," Capt. R. H. Horton, of the First Infantry, National Guard of California, Major David Wilder, Commander Battalion, held their annual target excursion and picnic at Esplanade park, Marin county, on Thursday.

Mount Hamilton.

The site of the Lick observatory—to be built from the donation of \$700,000, by James Lick, of San Francisco, is on the crest of the above named mountain. Its elevation is 4,350 feet above the sea level. It is distant, south-easterly, from San Jose, a trifle over 25 miles by road, and perhaps 18 miles in an air line.

Last week, by the kindness of our excellent friend, Mr. S. P. Sanders, landscape photographer, of San Jose, we made a very enjoyable trip to the summit of this soon to be famous mountain. Following the grand avenue, leading to Alum Rock, four miles, we come to Lick avenue, branching off to the right and extending to the very pinnacle of Mt. Hamilton. The maximum grade is one foot in sixteen. When finished it will be entirely macadamized, and a "spanking team" can be driven at good speed over the entire route. Gradually rising the hills which overlook the San Jose valley, we pass over the ridge into Hall's valley—a magnificently appearing meadow at this season. Then we climb a higher ridge, overlooking valleys and ordinary mountain tops, and with a slight descent enter a delightful glen, through which passes Smith creek—a sweet water river as clear as crystal. This place is seven miles from the summit by the grade. We reached it by trail in less than four miles. Below, the views are delightful and grand, but approaching the summit they rise almost to sublimity. The gradual winding upward by the road will afford the tourist a scene of lingering enchantment. Crossing the breast of the mountain in five zigzag lines, the road gives a final sweep around the crown, bringing the traveler upon the very crest of the pinnacle, unfolding to him in the near foreground mountains of little less magnitude but equally grand and bold, and in the distance, east and west, the larger valleys, the ocean, and the Sierra Nevada. The ever-varying hills and valleys are at this season of the year rendered more than usually beautiful by their green and brilliantly flowered covering. A few rods east of the highest pinnacle is a point of very perfect echo, which will afford much interest to visitors. Easy of access, just northerly, are other peaks which will also attract attention. We do not believe the people of San Jose are yet aware of the importance of their public spirit in constructing this grand and free highway to the hill of science that the God of nature so kindly set up and Mr. Lick has so grandly brought to light upon the very borders of their beautiful garden city. Of all the noble bequests made by James Lick, none, we believe, will ever afford his name so many pronounced blessings as the work here-mentioned.

Several miles of the road are yet to be completed by the contractor, Mr. Derby, who has to his credit pushed his work forward with great zeal. A grand Centennial Fourth of July celebration, would not be inappropriate on the completion of the Lick avenue.

As we are personally informed of the manner in which Mt. Hamilton received its title, we would here add that it was named by Prof. W. H. Brewer, of the late State geological survey, after his intimate and personal friend, Rev. L. Hamilton, of Oakland. Prof. Brewer, while stopping at San Jose with Mr. Hamilton, invited the latter to accompany him on a geological excursion, during which Mr. Hamilton was the first of the party to visit this mountain, leaving marks of his visitation. Mr. Hoffman, of the surveying party, now in this city, will verify this statement.

How to Have Warm Water.

The luxury of warm water constantly on hand in large quantities is something which our readers do not often enjoy. The method of securing it which is generally in use in city houses is expensive, and any contrivance which will cheapen the luxury and place it within the reach of thousands of homes, we conceive to be a public benefit. For this reason we quote for our readers a paragraph which we find in the *Los Angeles Express* of recent date, as follows: "We examined an invention this morning at Swigart & Huber's which is destined to create a revolution in heating water in houses for the use of the kitchen and the bath. The inventor, Mr. James T. Stewart, who is a workman in Swigart & Huber's, explained to us the principles of his invention, and we are disposed to think that he has really evolved a most magnificent problem in the economy of housekeeping. His invention consists simply of a section of copper pipe which fits on the flue of the stove. It is filled with tubes, through which the smoke and heat arising from the fire pass. The water is conveyed by means of a pipe from a tank, which may be located on the roof or in the attic. This connects with the tubular section, and the water in passing through it becomes heated, then passes into another pipe and ascends to the tank. As the hot water is drawn off, fresh water enters the tank from another pipe, which is supplied with a self-adjusting valve. Thus the water in the tank is kept constantly at the same level, and as it is continually circulating to and from the tubular section, it is maintained at a temperature of heat consistent with the degree of fire in the stove. The tubular sections are made to suit every sized stove, and as the tubes, although of copper, are fitted on the side next to the water,

they are very strong and there is no danger from verdigris. By this simple apparatus any house can be supplied with hot water at all times. A small family can be accommodated with this desirable element just as well as a large one. It does away with the cumbersome coils of pipes which are required by the old method, avoids the necessity of an expensive copper boiler, and places the poor man's house on an equality with that of the rich as regards the luxury of heated water. The entire outfit will hardly cost as much as an ordinary heating boiler such as is now used in connection with the ranges. The water tank may be of wood, and need cost but a mere trifle, and the pipes leading to and from it may be placed in a house at a very moderate figure."

The Corning Tunnel, Colorado.

We condense the following facts concerning the mining and milling operations of the Corning tunnel company from the *Boulder (Colorado) News*:

The mill is being erected by the Left Hand creek, directly below the mouth of the tunnel which is being driven through Gold hill. The new buildings are a framed house over the mill, 36x64 feet, with shed additions around, furnishing room for offices; a boarding house, 30x44 feet, and stable, 30x30. The main mill building is made large enough to cover 40 stamps. Fifteen only will be set up at first. The veins so far cut by the tunnel yield free gold ore, soft iron and copper pyrites, and the process of treatment adopted is the simple one ever found most profitable in this country. The harder rock will first be broken by jaw crushers, thence fed into the batteries of the common stamp mill, using the common amalgamating tables, only that the copper plates for this mill have a coating of silver, regarded as an improvement. What gold escapes amalgamation in passing over these galvanized plates goes off with the tailings, and these are to be concentrated.

A 60-Horse Power Engine

Is provided to drive the machinery. And as soon as the company feel warranted in making the additional outlay for a turbine wheel, they propose to use water power, except during the colder winter months. Wood at the mill costs only \$2.50 per cord, so that steam is not costly. The country around is well wooded, and it will be a long time before there is a scarcity of fuel.

The Bonanza

is the name given the great vein last caught by the tunnel, 600 feet in. This vein of ore is being developed for supplying the mill, or, rather, the mill is erected to make available the ore brought to sight in this mine. The Bonanza vein is cut at a depth of about 400 feet from the surface of the ground. Eastward on the Bonanza the drift extends 200 feet, disclosing a continuous pay, varying very little from an even width, the average thickness of the vein of mill ore being about three feet; or, to be more exact, the variation is from two feet and four inches to three feet and six inches. West the Bonanza drift is run 140 feet, in which there is 25 feet of barren ground—the remainder being much the same as east, with pay in the breast of the level. No Colorado mine has yet developed a better showing for ore.

Will it Pay?

To satisfy themselves of this, they had 75 tons run last year, in a little old stamp mill on the creek. The result was satisfactory. The new mill is being constructed with the view of making the most of a large bulk of ore of low grade. It is well known that in California and Australia free gold quartz that yields \$10 per ton is made to pay handsomely. This is done by figuring closely, and seeing to it that the practice meets the figures. The ore brought to sight in these large Corning tunnel veins ought to pay if it yields no more than \$10 per ton.

The Corning tunnel was started by men who had in view the conduct of a mining scheme in a sensible and systematic manner. Most failures of mining enterprises in this country are due to the building of mills before having ore to run, and doing business generally wrong end foremost, so that expenses outrun all estimates and all reason. This is the rock on which they split, and the rock avoided by the Corning tunnel company. This mining enterprise may be run as closely to estimates of costs as an Eastern cotton factory, or any other regular business, and that gold mining is not gambling, nor simply a venture, but a legitimate business, based on solid foundations, and to be perpetually and systematically pursued.

The Future of This Project.

The Corning tunnel is designed to channel entirely through the hill, a distance of a little more than a mile. Its course is from the north to the south, across the course of the veins, in order to disclose the whole metallic wealth of the mountain. It was here that the tellurite lodes were first discovered, and many of the richest of the class course the hill. These will be caught as the tunnel progresses. In time the mines opened by this tunnel must give employment to thousands of men. Eventually all the levels will be run, and even the stopping done, by machine drills. The day is not far off when the whole process of mining and milling ores in this country will be so economical and systematized that rock holding the value of \$10 per ton will become profitable, and grades much lower be available for concentration. It is difficult to comprehend now what value will then be put upon such property as the Corning tunnel.

A Miniature Quartz Mill for the Centennial.

There has recently been constructed at the Union iron works in this city, says the *Sacramento Record-Union*, a miniature quartz mill and a set of mining machinery, which is soon to be forwarded to the Centennial exposition at Philadelphia, and to be exhibited in the chief cities of the East and of Europe. The machinery, which is now exposed in front of the corner of Front and O streets, is sufficiently attractive to awaken the interest of the dullest, and in its beautiful miniature proportions causes the ladies who view it to declare it is "just the cunningest little thing." Probably a thousand people have called to see it within a week. It was built for a joint stock company consisting of John Reardon, Nelson Wilcox, William Atkinson (of Amador), S. S. Spencer, W. H. Doane and Mr. Farrier. The entire machinery is a perfect model of the largest and most elaborate quartz mill in this State, and is just one-third its size. It occupies a space 14 by 16 feet, and is so constructed that it can be taken apart and packed in its cases in 15 minutes, or taken from the boxes, set up and put in motion in 30 minutes. First is the horizontal engine, which is mounted on a miniature locomotive boiler and fire box four feet six inches, by two feet in size, which, in turn, rests upon a wheeled truck. The engine bed is two feet long, and the engine itself, though but four inch stroke and three inch bore, is as perfect and complete as the largest, having every appliance and attachment used in the heaviest engines. Its nominal capacity is two and a half horse power, and it is finished up elegantly, with polished surfaces, a walnut jacket to the cylinder, silver gauge and spring-hall governor, and weights, with boiler, fire box and truck, but 700 pounds. Next to the engine stands a Wilson amalgamator, one-third the usual size, and beside it the best pattern of settler and three settling tanks.

Lastly comes the quartz mill. The mill is mounted in hack walnut and California laurel frame, oiled and polished, and is in two sections of two batteries each, five stamps to the battery, or 20 stamps in all. Each shoe weighs 30 pounds, has three inches drop and a three inch face. Each mortar is 19½ inches long and has No. 60 wire screens 2½ by 16 inches each. All of the stamp rods are polished, and the rough iron work neatly painted. The upright frames between which the stamp rods play are made of heavy black walnut beams with cross guide beams of California laurel. These upright frames are in two sections and are set into the bed frame, held by wooden keys and braced by hog chains tightened by swivel stirrup links. To loosen the latter, knock out the keys and lift a section to its packing box is but a moment's work. The mortars and dies are of cast iron, the former being fed from the back the same as in the larger mills. Nest black walnut hinged levers serve to lock the stamp from dropping when cleaning up time comes. All the usual rifle boxes, water feeds, pumps, troughs and other attachments of a first-class quartz mill are to be found in front of the mortars, the troughs and boxes being copper bottomed and very neatly finished up. The entire weight of the mill, pans, attachment, engine and boiler, will not exceed 5,000 pounds.

This mill is capable of crushing from one to two tons of stuhhorn rock and passing it through all the processes in a few hours of work, according to the claim of the company. With the mill a cabinet of California and Nevada ores will be taken on, and several tons of silver ore and gold quartz. It is the intention of the company to regain the money they have expended in its construction by exhibiting the full process of reducing ores as practiced in California and Nevada quartz mills. It is also intended to use the mill as prospecting and test machinery, as it can be transported to almost any locality at a small cost, and will do its work as thoroughly as the large mills. It is intended to have it in operation in Philadelphia by the first of July, after which it will be taken to the chief cities of the United States, and then across the Atlantic, but will be returned to Sacramento by this time next year. Mr. Reardon will be working exhibitor of the machine, and Messrs. Wilcox & Doane business managers. Prior to leaving for the East the mill will be set up on J street and exhibited here, this being in compliance with the request of a great number who have seen it in the shop, and desire to witness it at work. As a specimen of mechanical neatness it is a most creditable exhibit for the Union iron works, and as a lively exhibition project it is sufficiently venturesome to warrant the wish that its projectors may succeed.

ANOTHER MILL COMING.—The *Boulder News*, speaking of the North Boulder silver mill says: The operation of this mill forms an advance step in Colorado mining. It demonstrates that low grade silver ore may be profitably worked by a mill the first cost of which need not exceed \$20,000. The wealth of the mines is in the low grade ores, and by this process they may be worked to profit. It is not only a very economical process, but the machinery is not liable to get out of order, and the extraction of the silver is very close. It is the purpose of Superintendent Cash to erect a mill of this kind at Georgetown.

The road to Yosemite valley is now open via Chinese Camp, and passengers can reach the valley from Stockton in 34 hours. The Centerville and Yosemite road is also open.

Protecting Steam Pipes.

In our issue of March 11th we described a covering for boilers, used in Germany, which resembles that used at the San Jose mines, Egan canon, Nev., the latter of which a correspondent describes for us as follows:

Take pulverized clay from the gouge of the vein, two parts; sifted wood ashes, one part. Wet and mix to the consistence of plastering mortar, with common flour paste made pretty thin, adding plastering hair or any short fibrous material such as old hoisting rope chopped into lengths of one inch or thereabouts. Apply this mortar in one or more coats of say half an inch in thickness. It will adhere well, and harden quickly from the heat in the pipes. A coating about three-quarters of an inch thick applied to a three inch steam pipe 420 feet long, 60 feet of it horizontal, 30 feet of vertical, and the remainder going down a main incline at angle between 50° and 60°, up which was circulating a strong draft when the cold was from 10° to 35° below zero, so effectually prevented cooling of steam at 400 feet from the generator that the steam was only two pounds lower at the pump than at the boiler. Of course pulverized asbestos or other more non-conducting material would serve, in lieu of what we used, a better purpose.

Mining at Magnolia.

A correspondent of the *Boulder News* writes from Magnolia, Colorado, as follows:

This is a lively mining camp and is growing more so. Day by day brings new arrivals. People from Georgetown, Central, Boulder and elsewhere are seeking to share with the earlier settlers in the harvest of rich gold ores which everybody acquainted with the district concedes to exist. Prof. Weiser, of Georgetown, is here. He states that he never saw such rich ores before. Those sought for are of the tellurite class, varying from calaverite to sylvanite, with all the intermediates. The veins are many of them immense, but the larger ones generally carry lower grade of ores than the smaller.

The mine just now occasioning most excitement is the Kit Carson. It is a splendid strong vein, with a well defined crevice 18 inches wide, showing a good deal of sylvanite and perhaps some calaverite. This lode has a history similar to many others. One person after another laid claim to it, each in turn showing a little work, and then leaving it for somebody else who had more faith to enter after the claimant's sixty days had expired.

New lodes are being struck daily, and some look extremely well. Prospecting has been extended as far as Coal creek, and is reported to have been attended with success.

AFFAIRS AT LITTLE COTTONWOOD.—A correspondent of the *Salt Lake Tribune* writes as follows from Little Cottonwood, Utah: The weather is warm and delightful, and the beautiful snow is fast melting away, only about five feet remaining, and on some of the most exposed points Mother Earth is beginning to put in appearance. The roads are in bad condition, and but little ore is being shipped, but that difficulty will be soon overcome; and the tramway will be in operation by about the 20th of the present month. It is now opened up and cars running within two miles of this place. Mr. Goss has a large force shoveling out the remaining distance. The tramway will do a rushing business this season, and it is certain the ore shipments will be nearly double that of any previous summer since Cottonwood has been known as a mining camp. Business is looking up, and all anticipate booming times this year. Our merchants are laying in heavy stocks, and are fully prepared to supply the demand, let it be ever so heavy. The mines are considerably troubled with water from the falling snow, but a few more weeks of warm weather and that difficulty will be over. Then look out for lively times, as the mines never looked as favorable as at the present time.

THE C. & C. SHAFT.—The C. & C. shaft will soon have attained the depth at which the drift for the 1500-foot level of the bonanza mines is to be started. The station for this connecting drift will be opened at the depth of 1,273 feet, and they are now within 12 or 13 feet of this point. In about a week they will be ready to begin opening the station. When the station is completed they will start a drift from it to connect with the drift now being run from the 1500-foot level of the California. This last drift is already well out toward the shaft. In the large room in the basement of the hoisting works, where stands the big pumping engine, a foundation is being laid for an air compressor. The compressor is on the ground and the foundation is almost completed. A new cylinder is shortly to be added to the big pumping engine, which will greatly add to the present power. The new cylinder will be placed behind that now in use, and the piston will work through the first into the second cylinder. Much heavy work is being done at the C. & C. machine shop. All the old shafting of the Consolidated—that is, all that is found to be sound—is there being worked over.

THE new machinery at the Consolidated Virginia for hoisting mining timbers upon the cages is found to work to perfection.

THERE is a good supply of water in the Carson river, and the mills are running on full time.

MECHANICAL PROGRESS.

How an Ocean Cable May be Broken.

Now that ocean cables have become matters of general interest and a break in one is a public annoyance, it is well to know a few points of the ease with which these threads of civilization may be snapped asunder. The report of Sir W. Thomson and Mr. Bramwell on the repeated breakages of the Direct company's cable suggests some very startling possibilities in connection with the new industry of cable breaking, which has been so rapidly developed. The report shows that the process of severing an ocean cable in 80 or 100 fathoms of water is very easy. A schooner of 80 or 100 tons has only to drop overboard an anchor or grapnel, to which is attached a stout Manila rope, and with a wind that will enable her to cross the track of the cable at a speed of five or six knots, the force thus applied is sufficient to sever the strongest cable without raising it to the surface. It is evident that this could be done in such a way that only the skipper and one or two besides would be in the secret. It is also clear that a small steamer, well handled, would do the work far more effectually than a sailing vessel. In this way the cable of the Direct company has been broken four times in six months, and as yet the dastardly scoundrels who have done the mischief have not been detected. It is believed that

A Ring of Speculators

On the Stock Exchange in New York, having confederates in London, are at the bottom of it. Their plan is to purchase Anglo stock when low, and on the breaking of the Direct cable an immediate rise follows and a handsome sum is pocketed. Let us now suppose that, emboldened by success, these speculators should resolve to operate on all the cables which connect America and Europe, what gigantic fortunes might be made by skillful manipulators who knew that at a certain date telegraphic communication between the two hemispheres would be cut off.

How the Work is Done.

All doubt has been set to rest as to the causes of these breakages, by the report of Sir W. Thomson and Mr. Bramwell. After a most careful examination of the fractured ends, which were taken up, these gentlemen declare that "these breakages were not due to any decayed or imperfect condition of the cable, and also that they were not due to the chafing of the cable against a rock, or to any influence of an abrading or of a crushing character, but that the breakages have occurred in a perfect cable, and through thoroughly sound metal, and have been caused by the whole having been torn asunder under a violent tensile strain." They pronounce the cable to be in as good a condition as when first immersed in the sea, and to be of a very strong description. Further, they declare that no fishing schooner, dragging her anchor, could have sufficient force to break the cable, and that even if raised by an anchor it would not be broken." But, in reply to the question whether the cable could have been broken on purpose by a sailing vessel, they say: "The fishing vessels' cables are certainly strong enough to break the electric cable, if, as we are informed, they are from seven to nine Manila rope, as the breaking strain of seven Manila rope is as much as 14 tons. Thus their tackle is in itself sufficiently strong, and it seems to us clear that with wind enough to render a speed of five or six knots attainable by sail, a sailing vessel of eighty tons could, if handled for the purpose of doing so, break the cable without lifting it to the surface, and that with a steam vessel so handled, the operation would be still more easy." It is quite time that this dangerous pastime were ended and this noble breaking ring brought to justice.

GAS-MADE IRON.—Ironmasters in Staffordshire do not regard it at all as a promising feature in relation to the future of their trade with the United States, that the ironmasters of Pittsburg are making arrangements for increasing the supply of well-gas to be used as fuel in the working of their mills and forges. As is tolerably well known, Messrs. Graff, Kennett & Co., with some few others, are already using fuel of that class brought to Pittsburg from wells many miles off. It now transpires that about 20 iron-making concerns have formed themselves into a company, with a capital of \$200,000, to convey to Pittsburg the gas of the Burns and the Delamater wells, in Butler county. This project means the bringing of the gas a distance of 35 miles. At one time it was thought that difficulties almost insurmountable would be found in overcoming the frictional resistance due to so great a length of piping. In this case it is proposed to meet the difficulty by increasing the capacity of the pipes from seven inches for the first seven miles to 12 inches in the last seven. If, after this, the pressure should not prove sufficient at Pittsburg, then it has been resolved that pumps, similar to those used on the oil lines, shall be placed at intervals along the 35 miles. The line of pipes will cross the Allegheny river at the Sharpsburg bridge, and extend along the line of the Allegheny Valley railroad to the city.—*American Manufacturer.*

The Fish Torpedo.

The Whitehead or fish torpedo, says the *London Times*, is the object of continued study and experiment at the Royal Arsenal, Woolwich, and other places, in order to further increase its powers, and to construct devices to resist its attack. With the improvements contrived since it has been in the possession of the government, the torpedo boat can be set to run a straight course of a thousand yards under water and explode on striking its object; it can be arranged so as to half cook or full cook its trigger when approaching the object at which it is directed, and to rise near the water line or sink to the keel of the enemy's ship, as may be desired. If it misses its aim, a safety pin is released, and the torpedo goes quietly away, to be recovered at any future time. Its attack, however, could, it is thought, be effectually guarded against by surrounding the threatened ship with a strong net about 100 feet from the hull, and this difficulty, which is not very great, is now being faced. The weakest point of the instrument is, that being propelled by an air engine the speed naturally decreases with the decreased pressure in the air chambers, and although a very high rate of speed is insured throughout the entire journey, the pace is the least at the extremity of the course. There does not seem to be any help for this, but various experiments are being tried to reduce the weight of the torpedo, and by that means obtain increased velocity. It is also in contemplation to make a considerable reduction in the amount of the charge. Recent experiments have effectually proved that a few ounces of gun-cotton, when fired in contact with an object, will exercise an effect far more destructive than a much larger quantity placed at a few yards distance, especially in water; and provided the torpedo struck a fair blow upon the sides of a ship, it would make little difference whether it contained 500 pounds of gun-cotton or 50 pounds for either would burst the sides of the thickest armor-plated ship. What is wanted is a rate of speed which will tear through the enemy's network and a store of energy at the end of the race for another encounter.

ANOTHER SMOKE CONSUMER.—Mr. Benjamin Purnell, of Birmingham, Eng., has just discovered a very simple and yet ingenious mode of securing the consumption of smoke in steam boiler furnaces. His invention is applicable to all steam boilers, and it provides for boilers consuming their own smoke, without the aid of any elaborate apparatus. Just above the fire door of the boiler he bores a couple of circular holes of about two and a half inches diameter, and inserts two pipes, which run at the top of the furnace for about one-third or half its distance. A small pipe connected with the boiler drives a jet of steam into each of the pipes, which thus creates two strong drafts of air. This air is rarified by the steam, and is driven right into the center of the flame and smoke from the furnace, thus precipitating the carbon and preventing its escape in those dense clouds which cause such nuisance in large towns.

RAILWAY SPEED.—The following are the highest authentic instances of high railway speeds with which we are acquainted: Brunel, with the courier class of locomotive, ran 13 miles in 10 minutes, equal to 78 miles an hour. Mr. Stirling, of the Great Northern, took, two years back, 16 carriages 15 miles in 12 minutes, equal to 75 miles an hour. The Great Britain, Lord of the Isles, and Iron Duke, broad gauge engines on the Great Western railway, have been run with four or five carriages from Paddington to Didcot in 47½ minutes, equal to 66 miles an hour, or an extreme running speed of 72 miles an hour; the new Midland coupled express engines running in the usual course have been timed 68, 70, and 72 miles an hour. The 10 A. M. express on the Great Northern, from Leeds, we have ourselves timed, and found to be running mile after mile at the rate of a mile in 52 seconds, or at 69½ miles an hour. The engines used are Mr. Stirling's outside cylinder bogie express engines, the load being 10 carriages.—*The Engineer.*

A WOODEN WATCH.—We were shown yesterday, by engineer Matt Franklin, a wooden watch made by Victor Doriot, of Bristol. The case is made of brier-root, and the inside works, all except three of the wheels and the springs (which are metal), are of boxwood, while the face is made from a piece of the shoulder-blade of a cow, which was run over by a train and killed some time ago. It is an open-faced watch with a glass crystal, and is an elegant piece of workmanship, displaying wonderful talent in the maker. It does not weigh more than an ounce. Matt says he has carried the watch a day or two, and it keeps as good time as any watch he ever carried.—*Knoxville Chronicle.*

A LITTLE GIANT.—A trial was recently made at the machine shop of Johnson, Hess & Co., Philadelphia, of a new application of power, with steam, to a five-wheeled engine, for propelling city railway cars. The application of power is so decided that, under a pressure of only 40 pounds of steam to a diminutive engine of only four-inch cylinder and four-inch stroke, a large truck, with several tons of iron on it and some 15 men, was pulled and backed for several hours, without apparent resistance. It is the opinion of those who witnessed the trial that this little giant will pull 50 tons with ease, with no smoke or noise from the exhaust of any account.

SCIENTIFIC PROGRESS.

Impure Water.

A simple test for organic matter in potable water consists in dissolving therein a small quantity of white sugar. In a few days, if sewage urine, albumen, or any other organic impurity be present, the water becomes white and milky from the development of certain fungoid growths. Prof. Frankland, F. R. S., presented a paper on this subject to the Chemical Society of London, as long ago as February 2d, 1871. In this paper he advanced the theory that these germs are everywhere present in the atmosphere, but that they cannot develop in the sugar solution without the presence of phosphoric acid or some compound of phosphorus. The following comparative tests were recently made in this city to determine the value of Prof. Frankland's suggestion in a practical way. Four eight ounce bottles were filled with water, and to each was added one gramme of powdered sugar. The first of these solutions, which contained boiling distilled water and no air, remained unchanged during the whole experiment, lasting 50 days. No. 2, which contained Croton water and a little air, began to exhibit a white sediment in nine days, which seemed to adhere to the bottom of the bottle. In two days the third solution, to which had been added five c. c. urine (or about two per cent), had a milky look; in three days a heavy froth on top, and in eleven days was perfectly opaque, and contained small white flakes; at the end of a month still heavier deposit and cloudy; in 50 days less opaque, heavy sediment. To the fourth solution was added six c. c. of a solution of phosphate of soda. The changes were more marked than in Croton alone, but far less than in that containing urine, showing that some other ingredient than phosphorus aids in producing the change. Neither two nor four are opaque at the end of 50 days unless shaken to diffuse the heavy sediments in them.

An English chemist suggests the employment of the neutral sulphate of peroxide of iron as an agent for

Restoring Impure Water.

The iron salt being added in a very delicate state to the water to be operated upon. The proportion in which this solution is to be added to the water is determined by the degree of impurity characterizing the water; and the proportions suitable must therefore be determined by careful experiment practiced from time to time, if the impurity of the water is found to vary. The water to be purified may be run into a tank or reservoir, and the solution of neutral sulphate added as it runs in, so that the solution may be well mixed with the water. A short time after the neutral sulphate is added to the water it becomes decomposed, and forms, with some of the impurities contained in the water, a basic salt, which is insoluble in water. The solid and insoluble particles of this new salt are precipitated, and, together with the impurities contained in the water, form a sedimentary deposit, from which the purified water may be allowed to run off, leaving the deposit in the tank or reservoir. A repetition of this precipitating process on other bodies of water which may be run into the same tank or reservoir will cause additional deposits, which, when allowed to accumulate to a sufficient depth, may be collected and removed from the reservoir from time to time.

Peculiar Growth of Wood.

At a recent meeting of the Academy of Natural Sciences of Philadelphia, Mr. Thomas Meehan called attention to the many varying hypotheses in regard to the eccentricity of the annual layers of wood in plants, which is sometimes so great that, as recently shown by a writer in the *American Naturalist*, the pith (in the common poison vine) is wholly on one side, and once in a while seems like a little ridge running along just beneath the bark. In the poison vine the greatest thickness of wood seems generally on the side between the pith and the object the vine clings to, and the writer referred to surmises that the rootlets coming out on that side may have something to do with this interior thickening. Another gentleman, Dr. Hickok, of Poughkeepsie, thought only those trees which sloped a little thickened chiefly on the under side. These hypotheses were inconsistent, and Mr. Meehan thought the true cause of the thickening of woody layers more on one side than the other had yet to be explained. The rooting on the under side could not cause the thickening of the wood, as *Wistaria* and many others which he mentioned, rooting on the ground as they ran, did not thicken in consequence; while *Ampelopsis* did, as well as the poison vine. The rootlets by which the poison vine attached itself to the trees had been referred to as being of some age; but this was a mistake, as in most cases, save some orchideæ and a few other plants aerial rootlets, like rootlets beneath the earth, were mostly annual. The whole root system of plants was, indeed, but the analogue of that system which existed in the atmosphere. Morphology had made a great stride when it pronounced all the parts of the inflorescence but modified leaves. Botanical science had yet to go further. The whole plant was but a modified leaf, roots as well as branches. The same general laws that we found in the aerial system, therefore, had their correspondence in

the terrestrial one. In the terrestrial system we generally saw a marked difference in the leaves and branches; but in some cases, as the arbor-vitæ and deciduous cypress, the two were so blended together that at the annual "fall" season branchlets and leaves all fell together. In these cases we saw that some of these compounds of leaves and branches—those the most favorably situated as regards nutrition—maintained a hold on life, and, once passing this critical time, had an indefinite lease of life thereafter. It was precisely the same with the rootlets of trees. They were the representatives of leaves, and myriads died every year. Only here and there one endowed with greater vital privileges escaped the annual "fall," and then it became a "root," with various terms of endurance. Aerial roots, used by some creeping vines, were under the same laws. Now and then one would find itself in a soft crevice of an old wall or in the decaying hollow of an old tree, and thus become a permanent feeder to the tree. In England the evergreen ivy had been cut down near the ground, after running for years over old ruins, and had continued to live on. But in these exceptional cases it was found that some of the rootlets, as the rule, annual, had found some soft place and taken on a permanent character—had become real feeding woody roots. He exhibited some old stems of *Ampelopsis Virginiana*, which for many years had been hanging unattached from the branches of a tree, and which had eccentric wood, as in the attached poison vines, and the surface was covered with aerial roots, which were produced and died annually.

Taking Down Speeches by Machinery.

When a flame is burning at the opening made in drum, at the head of which there is a very elastic membrane stretched, any noise or vibration, as by speaking or singing, will also set this flame in vibration, which vibration will differ in its nature according to the nature of the vibrations of the air communicated to the flame, and if now a rotating mirror is placed before the flame, revolved at a proper rate of speed, a series of images of the flame and of intricate figures will be seen in the mirror, and with lenses these figures may be thrown on a wall or a screen, and the figures thus thrown will appear in great variety, as various as the sounds which produced them, every sound having its own corresponding figure.

It is now suggested to employ a flame of high chemical intensity, so that it can make photographic impressions, and to replace the screen by a prepared strip, moving like a stock telegraph, at a proper rate of speed, so as to receive the successive impressions regularly in line; and if the various signs thus produced are properly interpreted as to the original sounds which have originated them, we will have a photographic record of speeches, etc.

Oil as Fuel.

At a recent meeting of the Scientific and Mechanical Society at Manchester, an interesting paper on the use of oils for fuel was read, from which we take the following:

In experiments as to the comparative value of coal and oil for the production of heat, a quantity of oil weighing less than five pounds was mixed with water, in the manner proposed for use, in a suitable apparatus, and without the aid of artificial draft burnt for 15 minutes with a flame 34 inches high and 2½ wide; a superiority over a similar weight of coal which is self-evident.

We have therefore, not only a cheap, but, including foreign sources, as great a supply of fuel in oil as in the stone coal; occupying in transportation less space and more easily handled.

A further, not sufficiently prized, advantage in the use of oil is, that a more constant heat can be maintained, as with addition of fresh coal to a fire there is a very considerable and rapid diminution in the heat. Secondly, being more easily controlled, a single man can mind quite a number of boilers, thereby lessening the present large force necessary. Thirdly, as a great advantage to steamships as preserving an equal calorific power, with much less weight.

LIGHT AND ANIMAL ORGANISM.—A favorite hypothesis is that the waking state is maintained in a great measure, if not wholly, by the constant summation of sensory stimuli; and that, by keeping the centrifugal nerves continually in a state of activity, the waking state reacts upon the processes of assimilation and decomposition throughout the body. This hypothesis rests upon a broad basis of circumstantial evidence derived both from physiological and pathological sources. Flatau has performed a series of experiments to ascertain directly whether stimulation of the retina by light really exerts any appreciable influence on the chemical change going on in the system (*Flatau's Archiv*, xl., 4 and 5). Rabbits were made to breathe pure oxygen instead of atmospheric air; the carbonic acid gas given off from their lungs was absorbed by a solution of potash, and quantitatively determined. Light was admitted to, and excluded from their eyes, during alternate periods of 30 minutes; the proportions of oxygen absorbed, and of carbonic acid given off during the intervals of illumination, being compared with those absorbed and given off during the intervals of darkness. The ratio as regards the oxygen proved to be 116:100; as regards the carbonic acid 114:100; thus confirming the results long ago obtained by Moleschott with frogs—results vitiated by the untrustworthy methods of investigation he employed.

Completed every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.

General News Items.

The Pope is 84. He may live to celebrate his centennial.

At a meeting of Plymouth church on the 18th, Henry C. Bowen was expelled by a unanimous vote.

The infant son of Princess Christina, born on the 10th, died on the 20th, at Windsor castle. The Princess progresses favorably.

S. S. BURETT has been compelled by reason of bad health to resign his position as Commissioner of the General Land Office.

There are 1,436,210 bushels of wheat, 502,207 bushels of corn and 233,507 bushels of oats in the Chicago elevators.

SIMON MAYO, while exhibiting a fire-escape in Chicago recently, fell from a fifth-story window, and died soon afterward.

BORN Daniel Drew and Commodore Vanderbilt are still seriously ill. The condition of the latter is more serious than for several days.

The President has nominated General E. F. Beale, formerly of San Francisco, as Minister to Austria, to succeed Orth, resigned.

The mental condition of the Sultan causes grave apprehension. He is subject to delusions, fearing that he will be buried alive or poisoned.

The Senate bill granting a site for an observatory to the Trustees of the Lick observatory with an amendment providing that if the land granted be used for any other purpose than for said observatory, it shall revert to the United States, has been passed.

The committee appointed by the New York bar association in reference to the charges against Charles O'Connor, have agreed upon a report, which will be submitted at the next meeting of the association. The report is wholly favorable to O'Connor.

A DISPATCH from Panama states that peace has been proclaimed between Guatemala and Salvador. The army of Salvador has surrendered at discretion. Valle, late President of Salvador, has embarked for San Francisco. General Santiago Gonzales, Commander-in-Chief of the Salvador army, has left for Nicaragua. Dr. Rafael Zedivar has been proclaimed President of Salvador.

FRENCH WORKMEN FOR THE CENTENNIAL.—A special dispatch from Paris, May 24th, says: The most careful and elaborate preparations are being made for executing the intention of the Legislature in sending to the Centennial exhibition at Philadelphia practical representatives of all divisions of industry. Auguste Des Montins is chosen to investigate and prepare an exhaustive report on educational matters. The Government is taking measures to secure intelligent and honest delegates from the trades organizations.

FROM THE CENTENNIAL.—Our readers will find in the present number of the PRESS a continuation of editorial correspondence from the Centennial. From all quarters the latest reports are the most favorable. There has been a steady increase in the receipts, and the criticisms on the great exposition, regarding both the display and its management, are exceedingly favorable. The position taken by the committee on Sunday exhibitions seems to receive the popular support. A grand success for the great Centennial exposition is evidently assured.

AUREOLA.—This is a valuable location on the northern portion of the great Constock ore belt, only a few hundred feet south of the Florida mine, and on the same large gold and silver bearing ledge now being developed by the Florida and Rock Island companies. Assays from the croppings give a high average in both silver and gold, and there are indications of a huge ore chimney between 600 and 700 feet in width. The company do not expect to have sunk over 150 feet to strike plenty of good ore.

RAILROAD COMMISSIONERS.—The Governor has appointed as railroad commissioners General George Stoneman, formerly of the army, now a farmer in Los Angeles county; Isaac W. Smith, at present residing in this city, who is said to have graduated at the Military Academy of Virginia, to have been largely connected with railroad engineering in the East, and to have constructed the Willamette canal and locks in Oregon; and John T. Doyle, of San Mateo, a well known lawyer.

THE LANCASTER (PA.) NICKEL MINE.—This mine is yielding about 6,000 tons of nickel ore per year. The number of men employed is 100. Improvements have recently been added to the extensive works. A new shaft has been sunk about 200 yards to the westward of the main one, 110 feet deep, through a solid body of nickel ore, being opened upward from a tunnel below. Eleven shafts have now been sunk, ranging from 110 to 140 feet in depth, and are connected by tunnels underneath. Four engines are in constant use, two at the mines and two at the smelting works, ranging from 25 to over 100 horse power, and one pump throws over 200 barrels of water at each stroke. A number of small railroad tracks have been laid, which run in all directions to convey the metal from the shafts to other convenient points, and an superior macadamized road has been built from the mine to the smelting works, paved with slag from the furnaces to the depth of at

least three feet, and extending a distance of three-quarters of a mile. The owner, Joseph Wharton Jr., of Philadelphia, has recently purchased the adjoining farm, containing 87 acres, at \$160 per acre. This mine had been worked prior to the year 1744, being noticed by the commissioner who divided Sadsbury township in that year, which appears in Rupp's History of Lancaster County. The mines are situated along the Gap ridge, about three and one-half miles to the westward of Gap station, on the Pennsylvania railroad, and were designated as the "Gap mines" by Governor Morris and by Thomas Penn in the year 1755.

A PARTY of gentlemen of Sacramento have organized a company to operate a new discovery, in the form of a bill of fire clay, located in Placer county, about 70 miles from Sacramento.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

MINING ACCIDENT.—CLOSE CALL.—*Chronicle*, May 20: On last Monday an accident occurred at the Eschequer mine, near this town, which gave a couple of the employees a close call. The cage brought up a car load of ore, which was run out and dumped by the car man, Robert Lindsey. In the mean time a miner stepped on the cage and was sent down the shaft, but the cage was barely out of sight when Lindsey returned, pushing the empty car ahead of him toward the shaft, not noticing the absence of the cage until it was too late—the car went tearing down the shaft, Lindsey falling on top of it. About 20 feet down it struck the timbering and turned over, catching Lindsey by the knee and holding him tight, for a moment only, against the side of the shaft, but Lindsey had the presence of mind to utilize that precious moment by grasping the cage cable, and had just succeeded in getting a strong hold as the car again got free and went thundering down the shaft. Lindsey clung on to the cable to the top and was saved. The man that went down on the cage heard the noise above, and fearing an accident, jumped off at the 300-foot level just in time to save himself, as the falling car damaged the cage very much. It is a tremendous escape, as Lindsey who has had one or two other narrow escapes in this shaft.

ILLINOIS-CALIFORNIA.—We hear that a heavy feeder of fine looking quartz has been cut in this tunnel, and that water is beginning to come in at the face of the tunnel, an indication that a ledge may be close at hand.

BUTTE.

MINING.—*Mercury*, May 20: The Federal Point mining company, in Nimeshew township, are at work driving a tunnel of 600 feet, by which they expect to fully open up their claim. Already they have met with several good paying streaks of gravel, but do not intend to commence working there until they have fully opened up the mine now in 300 feet, and are pushing forward as fast as possible. The ground is among the richest in the county, and when once opened will prove a good investment. Mike Robinson has charge of the work. He showed us a lot of gold he had taken out while running the tunnel, that proves that it is there in paying quantities.

EL DORADO.

THE NEW DITCH.—*Republican*, May 18: A force of men are now engaged upon the unfinished section of the new ditch, and it will be pushed to completion as rapidly as possible. In the mean time there is already a heavy supply of water as the supply this side of the gap is believed to be more than ample to supply every demand up to the time of the completion of the entire work.

THE main shaft of the Young Hermon mine is now down 60 feet, and another on an incline, starting from the same point, is down 45 feet. At that point a drift has been run through connecting the two, the distance being about 100 feet, and is solid quartz all the way. If, as is represented, it will work from \$9 to \$12 per ton, there is fabulous wealth buried there.

INYO.

DEFIANCE MINE.—*Coso Mining News*, May 20: The timbering in the main incline, or hauling shaft, has been completed, and the machinery will be set in motion next week. On the 80-ft level, between the middle and south winzes, in cutting west a very large body of rich ore has been developed. From the south winze, on the lower level, a drift has been run north 40 feet through a solid body of hard galena ore. One hundred and twenty feet south from south winze, on the lower level, a shaft has been run, and a solid body of hard galena ore has been developed. On vein No. 2, 40 feet south from main tunnel, a large body of hard and soft galena ore has been developed, the hard ore being about 10 feet in width. North of the main tunnel they are still working in the extensive ore bodies heretofore described, with no signs of diminution.

FRONTIER.

DEFIANCE FURNACE.—During the past week, in consequence of a mistake made in the manufacture of the improved water-jacket (it being some three or more inches too small), it was found necessary to remove it and put in its place the old one, which has been thoroughly overhauled and repaired. Consequently much valuable time was lost, and the product of bullion is quite small as compared with the weekly runs made heretofore. The old jacket is working well and turning out its usual amount. There were shipped during the week 420 bars, 190 bars being now on hand. In consequence of improvements in the building not contemplated at first, furnace No. 2 is not yet ready to start, but will undoubtedly be running in a few days. The new jacket is the improved one of Shepard & Rawlings, being several inches larger than the first one ordered, and will undoubtedly give the most satisfactory results. As ore is arriving at the furnace in large quantities and the company have some 30,000 bushels of coal on hand, we may expect a long run and large shipments of bullion when the two furnaces are in successful operation.

WORK on the mines of the Minietta Belle mining company is being vigorously prosecuted, there being 30 men employed on the mines and in bringing the water from Snow's canon, which water right was purchased by the company last week for \$3,000 cash. There are about seven miners' inches of water in the canon, which is quite sufficient for all purposes of this company, and several others. The water will be brought through pipes a distance of about four miles, and the pressure will be over 1,000 feet, which will carry it on top of Lookout hill and then be capable of throwing a stream 100 feet high. On the Minietta a shaft has been started, is now down 80 feet and will be continued to a depth of 200 feet. It is being driven following the vein at an angle of about 42 deg., and for the total depth thus far reached is through splendid ore. At a depth of 80 feet in this incline, a cross-cut has been made, showing an ore body of 31 feet.

PANAMINT.—We regret to learn from parties arrived from Panamint that the S. V. M. & W. Co.'s splendid 20-

stamp mill has at last been compelled to shut down for want of ore. We cannot yet believe, however, that the bottom of the ore body of the immense veins shown on the surface of this company's mines has been reached, and feel sanguine that the deep shafts now contemplated will pass through what is termed the "barren zone" and then will be encountered large and permanent bodies of ore. We understand it is the determination of the company to sink on the Wyoming and Hemlock shafts to the depth of from 800 to 1,000 feet to ascertain beyond a doubt whether or not they have deep mines. This, we think, would have been the best course to pursue in the first place—but better late than never. This company is entitled to much credit for its pluck and indomitable perseverance in the Panamint district, and we sincerely hope its further labors will be rewarded by the strike of a solid silver bonanza.

NEVADA.

SILVER MINES.—*Foot-Hill Tidings*, May 20: To be a mine one of our silver-bearing veins must furnish ore which will pay a profit above extraction and reduction. This by any process of reduction heretofore used here has not been possible, but high hopes, based upon the Fryer process, are now entertained that the silver may be taken out with profit. All along the foothills, five or six miles below Grass Valley, lying between the copper belt ranging along by Spencerville and the regular gold belt of Grass Valley, is a belt of ledges or veins of quartz which contains silver in larger quantities than gold. These are sulphuretted ores, and by common mill process yield up very little of either, though by assay they show \$40 to \$50 in silver and \$5 to \$10 in gold to the ton. Many of these are strong ledges, and if some method could be brought to bear on the ores to tame them or break up in any way the combination of silver and gold with the base metals, so as to allow of the amalgamation of those of noble men with their mercurial affinity, much wealth would result therefrom. Here is an opportunity for Fryer, O'Hara or any other man to immortalize himself and at the same time to make an ample fortune.

PLACER.

DITCH FLAT NEWS.—*Forum*, May 18: The Central claim cleaned up on Friday and is being refitted, so as to wash on a lower level and pass the tailings through the little Pine Top claims, the right of way so to do having been obtained from the owners of that claim. The Dunning claim is still being worked. The Franklin is still plugged; the Superintendent has had a crew of men shoveling the debris away from below, but the loose material near the surface falls into the shaft in such quantities that he has put in a string of pipe leading up the tunnel to the shaft with the intention of washing it out from that point. He will no doubt have this claim washed again in a few days. The Ledger claim had the misfortune of having the mouth of the small tunnel leading into its shaft completely buried by a cave on Friday morning. The material and the situation being such that it took until yesterday to reopen it. The water at the time of the cave was immediately turned into the Yankee, so the delay would have caused but little loss, were it not that it compelled the driving ahead of the Polar Star is off pending the preparation of a powder blast. The Summerset claim has started in on their second run for the season, and are washing mostly at night.

AT GOLD RUN.—The Indiana Hill and Cedar claims are off cleaning up. It is expected that they will resume washing to-morrow. The Gold Run claim has at last got into position to continue washing and promising well this run. The foreman says that he is going to clean up at least \$200 for each 24 hours' washing. The Hoskins and Sachs claims continue washing to good advantage. The Cement mill at Indiana Hill continues to crush and disintegrate the rich blue gravel lying on the bedrock at that point. The gravel is quite rich and is paying at the rate of from \$10 to \$12 per cord. The Haggard, Haggard & S. S. Shaffer, the foreman, was delayed about a week on account of the distributor which connects with the derrick failing to work. It became necessary to send to Nevada City to have the change made. It works splendidly now. From the indications of the ground sluices the foreman is satisfied that the clean-up on the first run will prove beyond a doubt that this is the bonanza claim of the company.

RAYMOND TUNNEL.—The superintendent of the Raymond claim, W. H. Rogers, had a survey made in regard to their tunnel, which showed that it would require a length of 2,200 feet to tap the bottom of the channel—rather a heavy undertaking. They have ground enough where they are working now to run them through the present season; then by moving their giants and pipes a short distance to Chance Point ravine they have sufficient ground to last them two years longer. The running of the tunnel will probably be delayed for some time yet.

LITTLE YORK.—The second slide took place in the Empire mine last week, causing a little delay. The bank at this junction is about 50 feet deep. There is a strata of 80 feet of clay and large boulders passing through the center of the ground on an angle of 45 degrees caused the slide. This strata of clay does not contain any gold whatever, and coming in such large quantities was not appreciated at the time. It will interfere with their first clean-up, but will add greatly to the future prospects of the claim. Christensen Hill claim has completed an expensive tunnel 670 feet long, which will be brought into use in a few days. This tunnel will give sufficient grade to work through for several years. This claim has paid a large amount in dividends during the last few years, and judging from the way M. Enright, the foreman, is handling it now, still better results are expected.

PLUMAS.

DITCH HILL.—*Cor. National*, May 13: The Caribon hydraulic company have been repairing their flume and ditch and will have it in running order soon. They have had considerable trouble with their flume along the lava bluff near Butte valley, owing to the large rocks loosened by the melting snow falling down and tearing away in some instances three or four boxes at a time. The ditch was broken in several places by slides, and in one place the bank slid away to such an extent that they had to put a flume across which was 30 feet high. Mr. A. W. Keddie, the superintendent, is a man of energy and perseverance, and keeps hammering away at it, and will have the water through as soon as any one else could. This company have the finest water privilege in the county, and probably there is no better place in the county for a flume than Butte creek, just below Miller's house, and there is enough water now in the creek to run a score of "giants," and such will be the case until far into the summer. I am informed that the creek never gets so low but there is sufficient water to run any hydraulic claim in California or anywhere else. Two large "giants" will be used in the claim, with a pressure of from 350 to 380 feet. The main pipe from the bulkhead to the distributor is 22 inches in diameter. From the distributor to the giant, 16-inch pipe is used. When these tremendous engines commence to make war upon the rich gravel banks there will be lively times in that neighborhood. This company have their claim fitted up in good shape, and in consequence of the fact that the North Fork mining company have about 300 inches of water in their ditch below the pipe, and have commenced piping. They have opened their claim on Barker hill about a quarter of a mile below where they were piping last summer, which gives them a fall of from 350 to 400 feet. The water is not yet through the high bank, but a force of men are at work on the ditch above the pipe and are driving it along as fast as possible, but progress is necessarily slow owing to the vast quantities of snow in the vicinity of Leeson's hutte. The ditch from Ohio valley is now open and the water has been through for a day or two, but small in volume. In the course of a week, though, there will be

some 2-0 inches from this source. The big pumping engine which was formerly used to raise water from Ohio valley, has been removed to Cummings' hill, and will be used to force water up to the top of the hill, as soon as it can be put in running order. This water will be raised something like 300 feet, and it is estimated that about 76 inches of water can be brought to bear upon the hill by this means. Cummings' hill is known to be very rich, and there is no doubt that this will prove a paying investment.

HUNOARIAN HILL.—Superintendent Killey, of Hungarian, was in town on Sunday, and on being "inter-viewed" gave us the following report of good prospects. Two giants are steadily at work night and day, and with plenty of water they are making a big hole in the gravel. The flume is not yet in bedrock, but Mr. Killey thinks they will strike it before a great while. The gravel looks splendidly, and prospects first-rate. Twice, within the past week, it has been found necessary to clean up two boxes at the head of the flume, and the result was 45 ounces of the coveted metal. As they have only run a short time, on top dirt, and with a nice, this result is a splendid indication of big pay this year. It does us good to record flattering prospects for this company, for they have worked at a disadvantage for several years.

FAST BRANCH COMPANY.—Mr. Jos. Halsted, superintendent of this company, was in town on Wednesday, and gave us a call. He says that they have thoroughly renovated their ditch, and now have about 2,000 inches of water running through it. The claim lies below Shoo Fly, where the pipes will commence operating in a day or two. The ground prospects well, and with the advantage possessed by this company, in the never-failing water right, it will undoubtedly pay richly. We are glad that the company have at last got fairly to work. They have had a long struggle and an expensive one, and now will receive their reward.

THE BELL QUARTZ MINE.—The new company are progressing rapidly with their operations at Elizabethtown. The tunnel is being driven night and day, and the shaft now being sunk for the purpose of getting water for the engine is in a mass of decomposed quartz, which prospects well, and gives promise that a long lead is in close proximity. The mill and the machinery will be brought from Reno as soon as the road is in good condition. The chances of this being one of the best paying quartz operations in the county are the best, and it is fortunate that the property has fallen into the hands of men who have the means to open it in proper shape, and put up the expensive machinery necessary to work it.

SAN DIEGO.

A NEW MINING DISTRICT.—A correspondent of the Union writes from Julian, May 8th, as follows: "I have just received a letter from Joseph Voshay, who has kindly furnished me a few items from the Vernon mining district, in which he is now operating. Mr. Voshay states that they have several locations in the district; the principal leads being named the Washington, the Whitman, (an Indian name), and the Saratoga. The ledge of the latter crop very high, at about a mile and a half, and averages from two to six feet in width; the croppings assay from \$50 to \$1,000 per ton. The location of this district is about 90 miles south of east from San Bernardino, and 10 miles south of the boundary line between San Bernardino and San Diego counties. It is 25 miles from what is known as Indian Wells, the terminus of the railroad, a little north of east of that point, with a splendid wagon road to the mines. Doubtless Mr. Voshay would like to have the helping hand of capital. He says everything to indicate that they will meet with success. I notice, by the way, that an article in the Scientific Press speaks of this district and locates it about 20 miles from Palm station, near the terminus of the railroad. The assays in general of a diffused ledge is reported. Lucky Barney, Les of Lee district, is reported to have bought into the late discovery."

SAN FRANCISCO.

GOLD IN BERNAL HEIGHTS.—*Post*, May 24: Victor Bessaire, Secretary of the French mutual benevolent society, is so firmly convinced that he has discovered a gold-bearing quartz ledge on Bernal heights, that he has filed in the Recorder's office a notice of the location of 1,500 linear feet of the Enreka lode and Paris mill, and mining company. Monsieur Bessaire is not the first prospector who has discovered gold-bearing quartz on Bernal heights, but if he develops a mine there of sufficient richness to pay for working it, he will be more fortunate than the hundreds of other miners whom this section of the coast range has impoverished.

SISKIYOU.

SALMON ITEMS.—*Yreka Union*, May 20: Tonkins, Taylor & Rainey's mine, the Evening Star, still keeps up its "lick," and the "clean-ups" at the end of each month continue to attest that the owners have a good thing. The Morning Star mill is crushing some very good rock, and it is expected that the next clean-up will pay handsomely. Quite a number of claims have been taken up and are being worked. The Evening Star, what is called the second bench of the river, and the prospects bid fair for good pay to be taken out. At the forks of Salmon, with the aid of the water brought in by Bennett & Miller's ditch, a number of claims have been opened and are paying well. The indications are that there will be a large number of people visit the Salmon section this summer.

GIVE IT UP.—Owing to the water coming in so fast, the parties who took the contract to sink 50 feet of shaft on the Empire ledge have thrown up their contract after sinking 13 feet. The company are now undecided whether to put in a pump and go ahead with the shaft, or to run a tunnel and drain the ledge in that way. They are now testing their quartz with an assaet, and if the result is such as to warrant the company may erect a mill, as the mine is so that they can already extract considerable quartz. The ledge is of good width, the rock of excellent quality, and increasing in richness as they go down.

VENTURA.

THE OIL WELLS.—The Signal of May 20th announces that arrangements have been made for the thorough working of the oil wells and the establishment of an oil refinery at San Buenaventura. On Tuesday a contract was entered into between Adams and Thayer of this county, and Robert O. Page and Reuben Denton, of San Francisco, experienced oil men, who have secured the services of the very best refiners, wherein Adams & Thayer will furnish 6,000 barrels of crude petroleum per month, and to deliver it at a price to be named by what is at San Buenaventura. The refinery is to be erected immediately and the delivery of oil will also commence at once. Thus another, the most important of all industries, has been added to our list, and San Buenaventura is taking the start as the leading manufacturing town in Southern California.

Nevada.

WASHOE DISTRICT.

CORN VENTURA.—Gold Hill News, May 13: Daily yield, 600 tons of ore, keeping the mills all steadily running up to their full crushing capacity. The Brunswick mill will be repaired and ready to run again in a very few days. The ore slopes show little or no change in any part of the mine. The east drift on the 1500-ft level to connect with the C. & C. shaft is well advanced, and is being pushed ahead with all possible energy. The erection of the new 80-stamp mill, east of the C. & C. shaft, is getting well under way; the most of the foundation timbers are already framed, the stone foundations are being laid, and much of the machinery is already on the ground. The erection of the amalgamating mill, on the site of the old Consolidated Virginia mill, is also being pressed forward at a very rapid rate.

of speed. The completion of these mills will add a crushing capacity of nearly 400 tons of ore per day to that now employed by the mine, and a like increase in the ratio of the hullion production.

CALIFORNIA.—Daily yield, 350 to 400 tons of ore. The ore-breasts on the 1500 ft level are opening up splendidly and promise a richer yield than any mine has ever yet made on the Ophir rock ledge. The California and Sacramento mills are kept steadily running on ore from the mine. On the 1600 ft level the north drift now being run to connect with the Ophir from the bottom of the winze tank below cross-cut No. 6 is in rich ore. The north drift on the 1400 ft level intended to connect with the Ophir at that point is making steady progress. The C & C shaft has reached the proper depth for connecting with the 1500 ft level of the Consolidated Virginia and California mines, and a station is now being opened at that point. The opening prospects are that the California will in a very short time be the leading mine in the world.

OPHIR.—Daily yield, 180 to 190 tons of ore. This amount of ore is more than the mill can crush, so that a large reserve of ore is being made. The mill is at all times running on the Ophir rock ledge. The ore-breasts are looking finely, and yielding ore of a good quality at every point. On the 1100 ft level a cross-cut east has been started from the main drift to connect with the upraise now being made from the 1300 ft level. The north drift on the 1600 ft level has a distance of about 112 feet yet to run to reach the point at which it is expected the ledge will be struck. On the 1700 ft level the drift and cross-cut have been cleaned out and repaired preparatory to starting the north drift toward the Mexican line. The mine is in better shape for the advancement of the prospecting on the lower levels, the extracting of ore, and the pressing forward of all kinds of work than it has ever been before.

BULLION.—The face of the combination drift, on the 2000 ft level now running in Alpha ground, has cut into the west clay wall of the ledge and may strike the ledge at any moment. There seems hardly a doubt but that this drift will strike ore, as the ore development in the Imperial mine has been extended so far to the northward as to almost insure such a result.

BELOHER.—The foundations for the new pumping engine and other machinery are well under way. Considerable quantities of the pumping and other machinery is now on the ground, and more arriving daily. Daily yield of ore, 450 tons. This yield of this ore is greatly increased over that of last month, the percentage of gold being nearly as great as at any time in the past. The air and drain shaft is completed down to the 1600 ft level.

JUNIA.—The southwest drift on the 1600 ft level is steadily advancing, with the face in very favorable quartz and ledge matter. On the 1800 ft level the southwest drift has tapped a strong flow of extremely hot water, which is considered a highly favorable indication of a strong mineral ledge.

LANY WASHINGTON.—Sinking the shaft has gone forward without interruption during the week, between three and four feet per day being added to its depth. The vein material at the bottom shows improvement.

ORIGINAL GOLD HILL.—The retimbering of the shaft requires more time and work than was at first anticipated. As soon as completed, sinking deeper will be resumed.

CROWN POINT.—On the 1700 ft level the main south drift is steadily advancing, the face still in quartz and low grade ore. The south winze from the 1600 ft level is down to the 1700 ft level, and is connected with the main south drift on that level, affording a much better ventilation in that portion of the mine.

CHOLLAR POINT.—Daily yield, 90 to 110 tons of ore, the assay value of which is \$33 per ton. This ore is taken from the old upper workings and is of a character of which the management has no reason to be suspicious. The erection of the machinery for the new shaft is making good progress.

ROSEBURY.—The water is drained to the 500 ft level, and this morning the station was cleaned out and everything found in good condition. The pumps have nothing whatever the matter with them, their stoppage being caused solely by a cave of mud and debris in the water tank.

IMPERIAL.—The extension of the north drift toward the Alpha ground was suspended a greater part of the week for the purpose of giving a better opportunity to start the north winze downward below the 2000 ft level. This winze is now down 15 feet, the bottom in ore assaying from \$150 to \$200 per ton.

AMAZON.—The south drift on the 300 ft level has been advanced 405 feet during the week. The drift is still following the wall of the ore vein, which is looking well. No cross-cuts have yet been run. The pumps are being put in position for resuming the sinking of the shaft.

BALTIMORE AND AMERICAN PLAT.—The ledge on the 1050 ft level still continues to show an improvement in both the north and south drifts on that level.

YELLOW JACK.—The cross-cut No. 1 on the 1400 ft level, is steadily advancing. So also is cross-cut No. 2 on the same level. The face of the last named drift is in fair ore. A cross-cut No. 3 is steadily advancing southward, the face in porphyry.

VIVIAN.—The mine is looking well throughout. The ore on the main track floor to the north is improving, also the south winze from the incline. The slope are yielding the best quality of gold-bearing ore. A quantity of ore is being shipped to the mill daily.

ORIGINAL COMBROCK.—It will not be long before the drift must intersect the ledge, as it is approaching in an oblique direction from the south end.

NORTH CONSOLIDATED VIRGINIA.—The station is completed and a large water tank is nearly finished at the 500 ft level. Sinking the shaft will be resumed by Saturday or Sunday next. The new pumping machinery has been contracted for in San Francisco, and will be forwarded at the very earliest opportunity.

OVERMAN.—Daily yield, 30 tons of ore. This ore is being extracted from the 800 ft level, and so far affords no new features in that portion of the mine.

UNION CONSOLIDATED.—The north drift on the 1300 ft level is still pushed ahead, the face in quartz and ledge matter of a very good quality. The cross-cut being run from the bottom of the south winze on the 1450 ft level, is also in ledge material, but has not reached the point at which it is expected to encounter the Mexican ore body.

GLASGOW.—A chamber has been cut out preparatory to sinking on the ore vein recently developed by the north drift on the 800 ft level. The winze has been sunk to a depth of eight feet, the bottom still in good ore.

MEXICAN.—The north drift on the 1450 ft level is steadily advanced, following the east wall of a ledge. Preparations for cross-cutting the ore vein at several different points on this level are going steadily forward. The north drift on the 1600 ft level of the Ophir is rapidly approaching the south line of the mine.

TRUMAN.—The new hoisting works and machinery are completed. It is the intention to sink the shaft, which is now down 187 feet, to a total depth of 300 feet, and then commence the extraction and milling of the ore now known to exist at that point.

JUSTICE.—The prospecting of the drifts both north and south, on the 800 ft level, are steadily advancing, with every prospect of opening up some fine ore developments in that portion of the mine in a very short time.

EAST OVERMAN.—Sinking goes ahead lively, and the most favorable prospects. The vein ore assure now proves itself to be fully 60 feet in width, showing plenty of both sulphur and chloride quartz.

SAVOIR.—The foundations for the new pumping engine are well advanced. Also the foundations for the hoisting and lowering the pumps into their places.

WEST BELOHER.—Retimbering the 400 ft station in the shaft has been completed. The west drift, on the

400-ft level, is in a distance of 285 feet, the face in low grade ore.

HALE & NORCROSS.—The immense stone foundations for the new machinery is being constructed at a very rapid rate, and the machinery is being placed in position ready for use at the earliest day possible.

ROCK ISLAND.—The north drift on the 850 ft level is steadily advancing, the face showing spots of fine quartz and occasional bunches of good ore.

MONUMENTAL.—Steam hoisting machinery has been ordered from San Francisco, and will arrive in a very short time. Preparations for the erection of new hoisting works are also being made.

SUPERIOR.—The quantity of quartz in the bottom of the shaft is showing a steady increase, and it cannot be long now before the main ore vein will be reached.

BROOKS.—The main shaft bottom is in ledge material intermixed with quartz of an excellent quality.

WARD.—The erection of the new hoisting machinery is fast approaching completion.

GOULD & CURRY.—The erection of the new pumping machinery is going steadily forward, as rapid a rate as is consistent with the permanency and durability of the work.

BEST & BELOHER.—This mine cannot do but little toward the development of the 1700-ft level until the new pumping machinery of the Gould & Curry is finished, ready to drain the water should any be found.

SILVER HILL.—The new station at the 550 ft level of the main incline is fast approaching completion. The flow of water remains unchanged.

SUPCOR.—Sinking the main shaft is going steadily ahead, the bottom still in fair anking ground, and the flow of water is still quite strong.

GLOBE CONSOLIDATED.—It is the expectation to soon commence cross cutting the ledge from the north drift.

DANBY.—Putting in the pump-hoist at the 400 ft station is making good progress. As soon as that is finished, the water will be extracted, and sinking resumed.

MINT.—Sinking the main shaft is still making rapid progress, the bottom in quartz and low grade ore.

LANY BRYAN.—Laying the foundation for the new and powerful pumping machinery is going ahead at a rapid rate of speed.

TRAM.—Sinking the main shaft is going briskly ahead, notwithstanding a strong flow of water.

ALTA.—The foundations for the new machinery are nearing completion. The pumping machinery will be first-class in every respect.

NORTH CARSON.—Arrangements have been made with the Virginia and Gold Hill water company for a full supply of water, for running the new hoisting works.

FLORIDA.—Cleaning out the main drift at the 400 ft level progresses rather slowly by reason of the large amount of water met with.

PHIL. SEHRIDAN.—The machinery is all working with the utmost perfection. The main shaft has been drained of water and put in first-class condition, and sinking resumed.

COSMOPOLITAN.—The raise above the main adit tunnel, near the north end, is still progressing upward, toward the surface, following the vein, and continuing in good ore.

PROSPECT.—Total depth of shaft 257 feet, 19 feet having been added to its depth during the week. Rock at bottom continues hard, but the Ingersoll drills are doing very effective work.

NAGARA.—Sinking the main incline is going ahead at an excellent rate of speed, the bottom still in soft ledge material.

SEVADA.—The face of drift continues in porphyry, quartz and streaks of low grade ore.

(Continued on Page 348.)

San Juan Mines.

Col. T. J. Anderson, the general passenger agent of the Atchison, Topeka and Santa Fe railroad, Topeka, Kansas, has just issued a pamphlet with maps and matter about the San Juan mines. From it we clip the following:

Perhaps no event could be more opportune, considering the deranged condition of labor and the depression of business throughout the country, than the discovery of the San Juan mines, in southwestern Colorado. Their extent, embracing as they do about 15,000 square miles, and their wonderful richness, exceeding in that particular the famous silver mines of South America, and far beyond any known in the United States, would seem a providential bounty, from which all classes and conditions may, for generations to come, draw support. West of Georgetown and Black Hawk, a little from Denver, runs in a southwesterly course the main divide of the Rocky mountains. Upon the extension of this almost unbroken chain, and in the southwest portion of Colorado, lie the San Juan mines. They are embraced within the counties of La Plata, San Juan, Conejos, Rio Grande, Hinsdale, Saguache and a portion of Lake. Upon the western slope of the main range, and upon the short, bold spur that shoot out westward from the main range, are found those rich silver deposits which have attracted thither thousands of stalwart men from all quarters of the world. Here are mines that it will take centuries to exhaust, and so numerous that it will take years of persistent prospecting to locate them judiciously. The principal silver mining districts are the Animas, Adams, Eureka, Uncompahgre and Lake, and with the exception, perhaps, of Lake, they are all within the limits of the new county of San Juan, while the discoveries next season will be made upon the mountains that lie along the Gunnison, the Uncompahgre, the lower Animas rivers, and along Cement and Mineral creeks, that empty into the Animas river at Silverton, and in the mountains southwest of Del Norte. The field for the prospector is rich and extensive.

THE NEW CALIFORNIA MILL.—A strong force is at work at the site of the new 80-stamp mill of the California mining company. It will stand a short distance east of the C. & C. shaft. The huge pits which are to receive the stone foundations of the batteries and engines are fast being excavated. The boilers are on the ground, also the battery blocks and other heavy timbers. When this mill is completed the pulp from it will be run to the present California pan mill and the pulp from the present stamp mill will be run to and worked at the new Consolidated Virginia mill, the former working California and the latter Consolidated Virginia ore.

The *Sunshine Courier* reports that the Caribou mine has been shut down, has been seized by workmen for wages due and will be sold for debt. Some bad management somewhere,

THE ENGINEER.

A New Coffier Dam.

The *Iron Age* says: On Saturday last there was launched on the Harlem river a coffer dam of novel construction, which will be used in connection with the work of the Dock Commission. The new coffer dam is formed by solidly framed wooden box walls, rectangular in section, and built with a flat bottom and disk, vertical sides, and of any length from 50 to 200 feet. A keel like that of a ship is attached to the bottom of each box wall, which steadies it in the water when afloat, renders it easy of movement by towing from point to point, and fixes it firmly on the bottom when it is sunk in position. The box wall is 15 feet wide from out to out, and its vertical sides are 35 feet high. Two of these wall boxes or caissons, placed parallel to each other, and from 30 to 40 feet apart, form the sides of the coffer dam, the ends being closed by A gates, as in a canal lock, the sills pointing toward the direction of the water pressure. These gates are hinged on the outer sides of the ends of the walls, and make a water-tight joint at the meeting of their leaves and at their abutment against the ends of the walls, by means of thick straps of vulcanized India-rubber attached vertically the full depth of the walls and gates. When needed for service, the floating coffer dam is towed to its place and carefully moored in position over the site of the work, care being taken that it embraces by its inclosing walls the entire area of operations. The hollow box side walls being divided into water-tight compartments, these are gradually filled with water by means of sluices arranged for that purpose, and under the weight of the water so admitted, the whole coffer dam slowly but evenly settles down on the bottom, the keels of the walls and gates biting into the soft mud and steadying the whole. The water-tight compartments are then filled to the top by pumping, and this additional weight forces the whole coffer dam downward in the soft stratum of mud that usually forms the bottom of deep rivers, estuaries and bays. In order to prevent under-leakage and to facilitate deep excavation within the enclosure, there are fitted to the insides of the perpendicular walls and ends a series of guides for heavy square piles, which hold the pile perpendicularly and close up against the walls, and so guide its downward motion into the deep mud in the same vertical plane as the wall face. To these piles are fitted broad wooden shutters, which fill the space between the piles, and when driven downward into the mud form a continuation of the wall to a depth sufficient to prevent leakage or disturbance of the sub-stratum when the inclosed space is pumped dry and excavated. These operations being completed, steam pumps, capable of exhausting the interior water at the rate of 20,000 gallons per minute, are set in motion, and the enclosure is quickly pumped dry and made ready for the excavators, pile drivers and masons, who work in the air, secure from danger, being protected by the inclosing wooden walls. When the masonry or other work reaches the level of high water, or even of half tide, the enclosure is again flooded, the piles with the shutter attachments withdrawn, and the hollow walls pumped clear of water. Then the coffer dam is again afloat, but it surrounds the work that was constructed within the enclosure. It is removed by withdrawing the bolts that secure the joints of the A gate, which is then opened, and the coffer dam is floated away, leaving the masonry surrounded by water.

Water Route from the Ohio River to the Seaboard.

The latest issue of the *American Manufacturer* notes an engineering project of considerable interest: In order to complete the connection of the Chesapeake and Ohio canal with navigation on the Ohio, through the Yonghiogheny, it is proposed to urge upon Congress an appropriation for the survey of the summit watershed and reservoirs of the proposed route, and also a relocation of the line in the upper part of Will's Creek valley. The former, it is stated, could be left until the work on the canal is actually commenced, and as there is no question as to the practicability of supplying the canal with water, the reservoir could be surveyed and built before the completion of the summit tunnel. The relocation of the line in the upper part of Will's Creek valley is not absolutely essential, as the present surveys have given a practicable line of canal. It is thought, however, desirable to make the lifts of the inclined planes more regular, which, in consequence of the complicated character of this portion of the route, has not been done in the existing surveys. Another proposition is a survey for an extension across the state of Maryland to the Chesapeake bay. This, it is claimed, will greatly enhance the value of the canal as a water outlet to the trade of Pittsburgh and of the Ohio river. The cost of this survey is estimated at \$15,000. It will be more expensive than the usual survey of such a length of canal line, because the great question will be that of water supply by reservoir and feeders, and this branch of the examination will require a thorough survey of the watersheds lying above the line of the canal, as past investigations show that an extension to the Chesapeake is impracticable without reservoirs.

Eads and the Mississippi.

Mr. James B. Eads, who has acquired a national notability through his undertaking to deepen the channel of the Mississippi by the jetty system, has written a pamphlet in defence of the theories on which his enterprise is based. He handles the report of the U. S. Commission of Engineers against the system without gloves, attacking vigorously the assumed facts and theories on which it is predicated. Mr. Eads' eminent success thus far toward the accomplishment of his great work peculiarly entitles his views on the subject of which he treats to marked consideration. The summary of his argument he gives as follows:

That increased volume will not permanently raise the flood line.

That outlets will not permanently lower the flood line.

That cut-offs will not permanently raise the flood line below them.

That the river water is not always under-charged with sediment.

That a relation exists between current velocity and quantity of sediment suspended.

That overpasses may cause deposits below them.

That the bed of the river is not too hard to yield.

That the statement that the river bed is a clay which resists the action of the current almost like marble, is an error.

It is upon negative assumptions to the above that the report of this commission against the system is founded. In most of his positions, if not all, we think Mr. Eads supports his theories by good and conclusive arguments. The limits of this article do not permit us to go into any discussion of the merits of the question or of the arguments used by Mr. Eads. It must suffice us here to remark that the practical results accomplished by the gentlemen afforded, even if we should admit that his arguments do not, some very stubborn proofs against the U. S. Commission.—*Vallejo Chronicle*.

MARRYING THE SEAS.—An American engineer, Mr. Spalding, has a project before the Russian government for turning the Black sea into the Caspian, which, if carried out, would make Mr. De Lesseps look to his laurels. The idea is to fill that great inland basin to the depth which it had many centuries or ages ago. A vast region about the Caspian sea is becoming a desert, and, according to Mr. Spalding, this deterioration was probably a primary cause of the great migrations from the East to Europe. He proposes to restore the sea to its ancient depth and area by making a great cutting, about 170 miles in length, beginning in the basin of the Caspian sea about 50 feet below the level of the Black sea, and cutting a channel 500 feet wide westward to such a point that at its western extremity it shall be about 35 feet deep. Thence to the Black sea he proposes a smaller and shallower cutting only 18 feet below the sea level at one end, and 10 at the other, and about 165 feet wide. With such a channel, widened and deepened by the action of the water, Mr. Spalding thinks that within 40 years the Caspian could be brought up so nearly to the level of the Black sea that navigation of the new channel could begin. This time could be shortened to about 25 years by the cutting of another channel connecting the Don and the Volga. The author promises magnificent results from the enterprise, political, military and commercial, to the empire to which he presents his scheme, and his memorial on the subject is now being translated into the Russian language by Russian military engineers.

PREPARING FOR THE FINAL BLAST AT HELL GATE.—The work of excavation at Hell Gate, preparatory to the final blast, has been finished several weeks, and the only work going on there at present is the pumping out of the water which filters into the mine from above, and the building of a piece of sea wall to protect the shore from the action of the current which will sweep against it as soon as the reef is removed. This wall, which will be 150 feet long, eight feet thick, and 12 feet high, is flanked at each end by a heap of debris, making an efficient protection to the soft earth of the shore. The testing of the various explosives used in submarine blasting has been going on for some time, and a dozen different preparations of nitro-glycerine were exploded on Friday last with a view of testing their efficiency for this work. The gun cotton prepared at Stonemarket, near London, has thus far given the most satisfactory results, and will probably be the explosive adopted. This material has not been much used in our government work, and no manufactory of it exists in this country. It will be placed in holes drilled in the pier and in the roof, those in the latter being pated five feet apart and extending half way through its thickness. About 30 tons of gun cotton will be required, which will be placed in position at the last moment, that it may be exposed as little as possible to the action of the water. The present appropriation will cover the expense of the final blast, and before that takes place it is hoped that a sufficient appropriation will be made to secure the removal of the debris.

The Diamond tunnel, Colorado, has intersected a new ledge at the distance of about 1,050 feet in the tunnel. This new discovery shows ore of a very good quality, and it is thought will prove valuable.

Mines and Mining in Montana.

The *Holena Independent* says: It is hardly necessary to tell our miners that it behooves them this year to put their best foot foremost. Self-interest would lead them to this if there were no other consideration of more than ordinary interest. We are running a race, as it were, with the other Territories. Before the close of the year we ought to be able to show that we have a better mining country, more gold and silver, and better facilities for making these metals reward our industry than any other community. It is pretty certain that we shall reap a great measure of the benefit of the crowded immigration which has flowed into the Black hills, and which, as the stupendous fraud which has lured them here becomes every day more transparent, will naturally seek an outlet into Montana. If our mines afford to these adventurers a reasonable hope of the riches which they were disappointed in obtaining in Costar's fairy land, they will stop among us and make good, industrious citizens. There can be no question among ourselves of the richness and variety of our mineral industries. Any one who has lived a year in Montana is satisfied of this; but the difficulty is in producing the same impression on the mind of others. It can be done if we only go about it in the right way. Strangers judge of others by what they seem. If our country pleases us it will please strangers as well. It is not surprising that in the first flush of the Black hills excitement a great many miners went away. It was natural that they should be attracted to a country where report said gold was to be found about the roots of the grass and was in nuggets along the beds of the streams. This was all very well for a stampede, but it will not do now. Something more solid and substantial is requisite to attract population. The public, which has been deceived once, will not be easily imposed on again. When it sees our mines at work, our miners earning a competence, if not riches, and an undeveloped area of still greater extent inviting energy and industry, it will be satisfied that we have the gold that the Black hills has not; but scarcely anything less than this actual experience will produce that conviction. As the Big Horn country fills up the tide of adventure will spread out and drift over the Territory. No single locality can hope to catch or retain the influx of people which will seek homes and employment in Montana.

A Cheap Window Ventilator.

Professor Kedzie writes us follows to the *London Sanitary Record*:

I propose a cheap window ventilator by which the air will enter in two thin layers, with an upward movement by which it will mingle with the warm air of the room so as to prevent sensible currents of cold air. Take two pieces of board a quarter of an inch thick, one inch wide, and as long as the lower bar of the window; three narrow pieces half an inch thick and one and a half inches long, one end being cut with the bevel of the window stool. Nail these pieces across one of the long slats, one at each end and one in the middle, placing the short side of each piece even with the lower edge of the slat. Nail the other slat on the opposite side of these short pieces, bringing the upper edge of the slat even with the square end of the short pieces. This will make a compound bar with half an inch between the slats, and one slat half an inch higher than the other when the whole is turned upon its edge.

Place the whole under the lower window sash, with the higher slat on the outside. The air can then pass under the outer slat, between the two slats, and enter the room over the top of the inside slat, having an upward motion which will cause it to mingle rapidly with the warm air of the room, and thus prevent any sensible draft. By thus raising the lower sash, a space will be left between the top of the lower sash and the bottom of the upper sash, through which another thin layer of air may enter the room at some distance from the layer at the bottom of the window. The air must also enter with an upward current, causing it to speedily mix with the hot air in the upper portion of the room.

This arrangement is especially adapted to secure safe window ventilation in bedrooms. If properly constructed and inserted, it will never cause sensible currents in the body of a room except when strong winds prevail, when we usually secure enough ventilation by the imperfect construction of our window casings.

OPERATIONS AT WHITE PINE.—We see by a recent issue of the *White Pine News*, that after being laid up four months on account of not being able to have work during the winter months, the Eberhardt and Anrora company mill started up on the 1st inst. During the vacation, the mill has been thoroughly overhauled from stem to stern, and is now in all respects as good as new. New shoes and dies have been placed in the pans, and much heavier stamps will be used in the batteries; as a consequence, considerable more ore will be crushed than formerly. Fifty tons will now be the daily average of ore put through the batteries. Various changes and improvements have been made throughout the mill, and it is thought she will now stand the racket throughout the summer, needing only ordinary repairs. There is not less than 1,000 tons of ore on the mill dump at the present time; all the mill teams are busily engaged in hauling ore from the mine, and no doubt is entertained but that the mill will be kept constantly running for the next six months at least.

USEFUL INFORMATION.

The Art of Skeletonizing Leaves.

A writer in *Land and Water* says: The subject having excited a little interest among some horticulturists lately, owing to the exhibition of some beautifully executed samples at some of the large provincial exhibitions held in the northern and midland counties of England, I took the liberty of appealing to a lady friend, who has been very successful as a skeletonizer of foliage, requesting her to favor me with the *modus operandi* by which she produces her specimens with such perfect completeness.

My informant states at the onset that this art of skeletonizing leaves and flowers would be found much less difficult of accomplishment were the nature and character of the various plants thoroughly studied at first. This is no doubt a very important matter. For instance, it would be but a poor direction to this learner to say, "Gather the leaves on a certain day," unless proper attention be also paid to the leaves chosen. They must have reached a certain degree of maturity, neither too old nor too young; and as all leaves do not reach this maturity at the same time it is obvious that care must be taken that each kind must be gathered when fit for use. The leaves of the magnolia, for instance, may be gathered when the plant is in bloom, varying in time from June till August. They will require from a month to six weeks' time to be well immersed, and so be easy to dissect, as the fiber is so strong. The leaves of the ivy rank among the most difficult, and, because of this peculiar heanty of the fiber, will amply repay the trouble involved in the preparation. These may be immersed from the beginning of May to October, but should be leaves of the previous year's growth. All leaves will not answer for dissecting, but those that have been most successfully operated on are from the magnolia, ivy, pear, rose, holly, orange, poplar, willow, elm, lime, service tree, Spanish and horse chestnuts and the oak. The leaves of the last named should not, however, be put into the same vessel with the others, as it affects them in an undesirable manner. Seed vessels may also be dissected in an admirable manner; such are those of the stramonium, winter cherry, poppy, etc.

To procure good specimens, put the leaves into a deep jar and cover them with soft water, which must not be changed; the jar is then to be put in a cool place. When, upon examination, the leaves are found to be soft, they must be carefully brushed in a weak solution of chloride of lime for a short time, to whiten the fiber, and afterward washed well in two or three waters and dried carefully between sheets of blotting paper or linen, after which they are ready for mounting. To make stems for this purpose, thread stiffened with gum is the most useful, and it has a natural appearance. The leaves may be formed into bouquets or wreaths, according to the taste of the operator, and should be placed under glass shades to preserve them from harm.

I have seen groups of leaves so prepared that formed acceptable table ornaments in sitting and drawing rooms; and it suggests a pleasant employment for the fair sex with which to fill up moments of leisure. It is evident that much discrimination in the selection of the right leaves is required, and a light and careful manipulation is also essential; and in the case of failure from the first attempt, no small amount of patience is needed to carry the operation through to ultimate success.

Light Weight Tin Plates.

A writer in the *Grocer* says that the canning trade has lately suffered great inconvenience from the fact that much of the tin plates suitable for the manufacture of cans are very light weight, ranging as low in some instances as 95 to 98 lbs. per box, when the net weight should be 112 lbs. There is no doubt that this complaint is well founded. As it is very difficult always to draw the tin sheets to the exact weight, a variation of three or four pounds is allowed. Anything from 108 to 112 lbs. is accepted as standard weight. For years such a thing as debasing the standard weight was unheard of, and a box of tin plates was considered as good as gold. Without arguing the question of the relative merits of the two systems of collecting duties on imported goods, it seems to be a fact that the standard weights of tin boxes under the ad valorem system remained unimpaired. As soon, however, as there was a change made from the ad valorem duty of 15 per cent. to the specific duty of 1.1-10c. per pound on tin, the idea occurred to some importers that the lighter tin the less the duty and the greater the profit, and the better the opportunity for competition. It is probable that the majority of the short weight tin sold to the packers has weighed in the neighborhood of 100 lbs. to the box, and that a comparatively small amount weighing as low as 90 lbs. has been imported. We do not say that tin plate of the weight of 90 lbs. to the box may not be useful for many purposes, not that the importers that have ordered this short weight tin have in all cases designed to impose it upon their customers for full weight, but we do say that it is not safe for packers of vegetables and fruits in hermetically sealed cans, especially of the

larger sizes, to use tin lighter than the standard weight, unless the quality of the thinner iron used more than makes up the deficiency in strength, which may possibly be the case, and now having their attention called to it they had better examine the weights of their tin.

Galvanized Iron Waste.

A Wolverhampton manufacturer has devised a method of utilizing the waste of galvanized iron, which is described as follows: He prepares from the skimmings of the zinc pots which are used in galvanizing iron an oxide of zinc containing a large percentage of pure zinc oxide by mixing the said skimmings with carbonate, oxide, or hydrate of calcium, or of other alkaline earths, or the fixed alkalies, and heating the mixture in a retort or other suitable vessel sufficiently to cause a decomposition, resulting in the production of zinc oxide and a chloride of the alkaline earth, or alkali soluble in water. He then separates the soluble substances from the insoluble zinc oxide by treatment with water. Otherwise, instead of heating the mixture as described, he boils it in water and obtains a similar result, when, after allowing the zinc oxide to subside, he draws off the water containing the soluble substances, and washes the zinc oxide with water to separate more thoroughly the soluble impurities therefrom. After the production and purification of the zinc oxide by either method it is dried for smelting or other purposes. The compound of ammonia given off during either process may be utilized. Those of the carbonates which are insoluble in water are not so effectual or convenient in the boiling process as in the heating process.

HOW TO PREVENT HIGH GAS BILLS.—This following, from the *Scientific American*, may direct some manufacturers to the road to economy in the matter of light: There are various other causes of high gas bills, which the household might well look to, but into which we cannot enter in any detail here. Prominent among these are the burners, a poor one of which may easily burn double the gas and not give half the light of one properly constructed. The ordinary type of burner, besides, burns out; and through the enlargement of its orifice, soon becomes very wasteful of gas. Another cause of waste is due to people trying to read or work by several lights located in a high chandelier or fixture instead of by one light brought near them. A single burner, one foot distant from the page of the book, will shed on that page 38 times more light than the same burner six feet away; or, in other words, the single burner located as first stated, will light the page as brilliant as six chandeliers, of six burners each, hung six feet from the book. The absolute quantity of light is the same at all distances, but is spread out over an area which increases with the square of the distance from the flame; so that it is obvious that lights are used very wastefully when they are placed far from the object which they are to illuminate.

GOOD HEALTH.

Diet Dispensaries.

In New York and Brooklyn, and probably in other large cities, diet dispensaries have been of signal benefit to a large class of needy and deserving people. In health the working classes can eat almost anything; but in sickness, unable to earn their daily bread, and quite ignorant of the way to prepare diet for invalids, they suffer as much from the want of knowledge as from the lack of means. Every intelligent person knows that recovery from illness depends more upon food and careful nursing than upon medicine; indeed, the conviction is growing in the public mind, as it should, that strict conformity to the rules of hygienic living would obviate the necessity for medicines, and dismiss to other professions the majority of medical men. There are many who depend upon such means as diet, nursing, sleep, and judicious exercise to restore the sick without resorting at all to so-called medicines. In this class are many physicians, who give indeed bread pills, harmless tinctures, and skillfully compounded innocent mixtures to satisfy the patient, and insist upon the utmost regularity in diet, sleep, bathing, and exercise, relying upon these agencies and the recuperative powers of nature to effect a cure. To reach out a helping hand to all who need, these diet dispensaries have been established. A depot is opened for the distribution of supplies, which are given only to those who bring an order setting forth the peculiar needs of the applicant from a physician approved by the managers of the dispensary. The food furnished consists of beef tea, broths and such diet as may be required, prepared from the best of material, in a cleanly and wholesome manner, under the direction of a master of experience and skill, who is under the supervision of a committee of ladies from the board of managers. The funds needed to carry on these institutions are obtained from memberships, from contributions, and from moneys realized from fairs and festivals held for the purpose. An officer of the society visits those who are recipients of diet, and, if they are needy, makes their case known and relieves them so far as is

in her power by private aid, not from the funds of the dispensary. Those who desire to purchase diet for invalids can do so on reasonable terms, the proceeds going into the general fund.

• There are many towns and villages containing a large manufacturing population where an institution of this character would do a great deal of good; as much to those actively engaged in the work as to the recipients of the benefit. "It is more blessed to give than to receive," and they who imitate the Great Physician in doing good to the bodies as well as the souls of men, receive more than they give.

The Danger of Eating too Much.

"Nobody ever repented of eating too little," was the sage remark of an old gentleman on the verge of 90, next to whom the writer had the pleasure of sitting at dinner the other night. The host was pressing him to take more and urging him in the usual phrase, "Why, you have eaten scarcely nothing!" Now, it is to be assumed that the old gentleman's words indicated one of the by-ways to good health, along which he had traveled through his long life, and to which he owed his present remarkably hearty condition; so it was suggested to him interrogatively that he had always been a small feeder. "Yes," he answered, "ever since I was two or three and twenty; up to that time I was a weakly young fellow enough, and I used to make the great mistake of trying to eat and drink as much as I could, in the hope of becoming strong. All my friends and the doctors barked me in my error; but fortunately I found it out in time and 'knocked off'—as your modern slang has it—more than half my usual amount of stimulants. I gave up the idea of making myself strong, and merely strove to make myself well, and I was contented with eating just as much as I could digest and no more. Of course it took a little time and experience to discover the precise limits; I could not adopt the golden rule of always leaving off with an appetite, because I never began with one, but by persistently erring on the right side, I got hold of one of the great secrets of life—the secret of knowing when one has enough, and after a year or two I became so much better that I used to find myself ready to eat a meal at any time, and by degrees actually acquired an appetite. Then, once found, I never destroyed it, but always determinately rose with the feeling that I could eat more. Naturally temptation grew stronger, but I was firm. I did not behave ungratefully to my stomach and immediately presume upon its increased powers by overloading it. I did not live to eat, but only eat to live; and behold me! I have no need to be very particular as to what I eat, even at my time of life; I have only to be careful not to eat too much." Here, indeed, is the great secret of a great deal that is amiss with many of us. We are in the habit of eating too much, more than our digestive powers can tackle, and that which is not assimilated more or less poisons. The system becomes overcharged and gives any latent tendency to disease within us every faculty for developing itself. The question is not so much what to eat as what quantity to eat, and nothing but a sharp lookout kept by ourselves can give us the answer.—*Tinsley's Magazine*.

A Reason for Cleanliness.

Poisons in the Air.

Pasteur, in his recent experiments on spontaneous generation has demonstrated that the germs of low organisms, bacteria, micrococci, etc., are everywhere present in the air; they settle on the skin, in the air passages, etc., and are ready to become developed in all cases where there is no individual vitality which prevents the growth of the inferior organisms, of which they are the seeds. Healthy people therefore will resist their ravages, but weak, sickly, and especially dead bodies, will soon be the victims of their destructive action. The air in hospitals contains myriads of them, and besides dried pus globules, spores of epithelial parasites emanating from diseased parts, and which are so volatile or light by reason of their almost infinitesimalism, that they hover continually in the air. After some time the walls become invested with them, and this makes old sick rooms so unfavorable for restoration of health. To prove this, Pasteur had a square yard of wall in the surgical ward of the Hospital la Pitié, Paris, which intentionally had not been whitewashed or cleaned for two years, washed with a wet sponge, and the liquid of the sponge expressed; one ounce of a black liquid was thus obtained, which, on examination by the microscope, showed large numbers of bacteria, micrococci, epithelial cells, pus globules, red globules, and irregular blackish masses of unknown nature.

Next comes Dr. Esbth, of Zurich, and examines in the same way the sweat from the face, axilla, breast, and thigh, and finds great numbers of bacteria, which appear to originate from minute bodies attached to the hairs in these regions, forming little nodules like accumulations of micrococci.

The lesson conveyed by all this, is: Practice cleanliness about every part of the body; it is not in vain that combing, washing, bathing and rubbing gives a feeling of comfort—this feeling is a hint of nature that the human system needs it.

Saturday Morning, May 27, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A Favorable Report, King's Patent Galley Supporter; Paul's Patent Amalgam Safe and Mercury Discharger; Gems and Precious Stones, 337. Mines vs. Stocks; Virginia City and the Comstock Mines, 344. The Centennial at Philadelphia; One of Our Notabilities Gone; Tahiti, 345. Notices of Recent Patents; Patents and Inventions 346.

ILLUSTRATIONS.—Paul's Patent Amalgam Safe and Mercury Discharger; King's Patent Galley Supporter, 337. Scene in Tahiti, 345.

MECHANICAL PROGRESS.—How an Ocean Cable May be Broken; Gas-Made Iron; The Fish Torpedo; Another Smoke Consumer; Railway Speed; A Wooden Watch; A Little Giant, 339.

SCIENTIFIC PROGRESS.—Impure Water; Peculiar Growth of Wood; Taking Down Speeches by Machinery; Oil as Fuel; Light and Animal Organization, 339.

THE ENGINEER.—A New Offort Dam; Water Route from the Ohio River to the Seaboard; Eads and the Mississippi; Marrying the Seas; Preparing for the Fluvial Blast at Bell Gate, 342.

USEFUL INFORMATION.—The Art of Skeletonizing Leaves; Light Weight Tin Plates; Galvanized Iron Waste; How to Prevent High Gas Bills, 343.

GOOD HEALTH.—Diet Dispensaries; The Danger of Eating too Much; A Reason for Cleanliness, 343.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 340.

MINING SUMMARY.—From various counties in California, Nevada, Oregon, Arizona and Montana, 341-42-43.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 341 and their pages.

MISCELLANEOUS ARTICLES.—Mount Hamilton: How to Have Warm Water; The Cornish Tunnel, Colorado; A Mixture Quartz Mill for the Centennial; Another Mill Coming; Protecting Steam Pipes; Mining at Magualla; Affairs at Little Cottonwood; The C. & O. Shaft, 338. San Juan Mines; The New California Mill, 342. Mines and Mining in Montana; A Cheap Window Ventilator; Operations at White Pine, 343.

DRE CANON MINES.—Concerning the prospect of this place a correspondent of the Salt Lake Tribune says: The snow having nearly all disappeared, and the roads once more become good, mining has started up with renewed activity for this season. The following mines are at work, and show marked improvement: Galsua, Pine Grove, AcBar, Don Pedro, Wandering Jew, Home Stake, Keystone, Joy, Mahogany and Leap Year. Those preparing to start work are the Ontario, Belle Wilbur, May Flower, Seventy-five and Rab Tickler. Taking this camp throughout, there never has been any time when its mines and prospects gave their owners more solid encouragement than at the present time.

MATHEMATICAL.—A correspondent writes the following query for some of our readers to answer: Tell me how to describe the greatest square in a given scalene triangle.

EDITORS PRESS.—Some of your numerous readers may be pleased to give a geometrical demonstration of the following queries: In a given scalene triangle, to inscribe a maximum square? Of all circular segments, the length of whose arcs are equal, which is a maximum?

PEN AND INK.

THE SULPHUR MINES.—This San Francisco sulphur mining company, which incorporated on the McWorthy sulphur mine near Rabbit Hole springs, are now working the sulphur beds systematically. The refining works are in full blast, and turn out on an average five tons of brimstone daily. This is hauled by teams to the Humboldt house, from which place three car loads a week are shipped to San Francisco.—*Silver State.*

CALIFORNIA PUBLICATION.—"Ben Nabo" is the title of a poem recently re-published by its generous spirited author, Hector A. Stuart, Esq., of San Francisco. It is accompanied by several shorter and later publications by Mr. Stuart.

Mines vs. Stocks.

Daily mors and more are the endless resources of our coast developing; our people are, in fact, just commencing to open up and bring to light the vast treasures hidden in our mountains and places California and Nevada in the front rank for mining enterprise in the world.

This mineral deposits of our coast are many and almost inexhaustible, and if they are worked judiciously must in each and every case be of pecuniary advantage to the owners. But there is one hindrance to the development of our section, and we are unable to see any means to remove it, that is the stock gambling. To work a mine is only possible to few individuals who have the good fortune of honanza bank accounts, and for that reason co-operation and stock companies have become a matter of necessity. When these stock companies first started and honest men had the management of them, our people, even the poorest of them, contributed to help enterprises which were the source of everlasting wealth of ourselves and our State. Money was expended fairly and honestly, and the fruits of the mines were given to the stockholders and divided among them. But alas! these times have passed. Our people had become too confident for unscrupulous men to allow their chances to pass. Companies were formed and capital but too easily obtained ostensibly for mining purposes, on ground which did not only never possess any metal-bearing lode, nor ever carry auriferous gravel, but had not even the intrinsic value of land that can bring a good potato crop. Large sums, the proceeds of stock sales and assessments, wandered into the pockets of sharps, and when a dozen of these swindling concerns had vanished, the success of one legitimate undertaking would give rise to another dozen and our people were duped and swindled out of their money till they grew tired of it. But we don't mean to say that all such enterprises were commenced with fraudulent intentions and on ground of absolutely no relative value; to the contrary, many a good mining claim lies to-day in California unworked because its progress was impeded by stock sharps, who, when they saw their game spoiled or were unable to prosecute it any longer, had to let it go, it has become infamous and there it lies covered with grass. And these same stock sharps have acquired a power which is detrimental to our best interests. If a mine is but on the board it is sufficient to furnish the means for the fitting up of costly offices, for the paying of Brussels carpets and princely salaries, sometimes even for the erection of enormous hoisting and reduction works, and many times thousands and thousands were expended for the purpose of teaching at the cost of the company the art of mining to a superintendent who chances to be second or third cousin to the lassing man, but who has never seen a mine before his cousin made the lucky stroke of becoming president. This game has been carried to such a point that our most promising mines are lying helpless for want of co-operation. People are too far in the hands of men who make it a business to gamble in mines or mining stock instead of working them legitimately, and nothing is more characteristic of that than what a stock sharp told us the other day: "If you have bonanza in your mine we on California street can sell your stock at two bits a share if we choose to do so"—and that man did not know silver from a piece of grindstone.

But this time will come when no such humbug nod-raking has any chance of success. Honest mining men make it a point to open the eyes of our fellow citizens, and it will henceforth be one of the objects of the MINING AND SCIENTIFIC PRESS to discard anything coming to our notice that does not bear on its face honesty and probability of success and that does not carry at its head names which guarantee a fair and legitimate expenditure of funds which our people contribute for the development of our section.

REMOVAL OF THE WIRE WORKS.—Among the acquisitions of our thrifty neighborhood are the Hallide wire works, which have removed from 113 and 115 Pine street to No. 412 Clay street, one door below the office of the SCIENTIFIC PRESS. Our friends will be pleased to learn that this establishment has recently increased its manufacturing facilities three-fold, and is now prepared to furnish all kinds of wire work in any quantities desired. Their range of goods is a wide one, embracing many articles in mining, mechanical and housekeeping operations. Many of these articles—the patent endless ropeway for instance—have become famous; while those which are of ordinary use are increasing to an extent which is almost innumerable. The work of this establishment is as famous for its neatness and thorough adaptability as for its superior strength. Most of the special merits of this now celebrated wire works have grown out of the peculiar wants of our situation, and Mr. Hallide, the head of the establishment, has done much toward supplying our special mechanical wants, some of which are of a complicated character. The works of this company have grown with the growth and strengthened with the strength of the mining, mechanical and housekeeping interests of the Pacific coast. It is now one of the largest establishments on this hazy street, and the SCIENTIFIC PRESS is proud to place it on its new list of neighbors.

Virginia City and the Comstock Mines.

NUMBER FOUR.

[By our Resident Correspondent.]

Last week's wandering brought us to the confines of the Sierra Nevada and even encroached a little upon its boundless in speaking of the old Sacramento claim. In speaking of the latter as being abandoned, it was not meant that the claim was abandoned but that work through the old shaft opposite the new works of the Utah had been discontinued. This claim itself is one of a good many that go to make up the 3,600 feet of the Sierra Nevada. This, the Hearst & Meredith, the Alls and a number of others, were consolidated into one company, which hesitates incorporation under the California law with the title of Sierra Nevada S. M. Co. The present officers are John Skes, President; W. W. Stetson, Secretary; W. J. Wright, Superintendent. Capital stock is \$10,000,000 with 100,000 shares. Annual meeting, second Tuesday in January. This is the most northern of the series of parallel claims on the Comstock, and is bordered on the south-west by the Union Consolidated, or rather by a strip of disputed ground which separates the two. The earlier workings of this company consisted of numerous short tunnels and shafts following surface deposits of high grade ores. Subsequently the hoisting works were erected at what is now called the old shaft, which was sunk to the depth of 825 feet. Some drifting was done at 200 and 300 feet, but nothing of importance until at the 700-foot level, within the past year, a drift was run north for 1,300 feet. This was through good looking ledge matter, with well defined walls, varying in width from 25 to 150 feet. The hoisting works at this shaft were considered perfect ten years ago and were ample for all that was then contemplated, which at the utmost was 400 feet. But having reached twice that depth they have come nearly to a limit of a strained capacity. Like nearly all early operators they concluded that the shaft was too far to the west and about two years ago a new one was started 1,400 feet north and 1,100 feet east of the first. Here preparations were made to mine in accordance with the necessities which had developed along the ledge, and hoisting and pumping engines provided for a depth of over 200 feet. The hoisting engine is a single Booth, and is run with a braks. The pumping engine is not used to its capacity, there never having been much trouble from water and almost none at present depth of shaft. Besides these two there is a smaller engine for the machine shop and an air compressor for all the work that is in contemplation. Ingersoll drills are used in the drifts, and a diamond drill is kept constantly at work prospecting ahead. System and cleanliness are decided characteristics about these works and some reader of Milton has posted in a conspicuous place the line "Order is Heaven's first law." This shaft is now nearly 1,700 feet down. There are three levels at depths of 1,000, 1,250 and 1,500 feet, in each of which there are both north and south drifts, and on the 1500 foot level an east drift also. From the 700 foot level of the old shaft an inclined winze is being run to connect with the 1000-foot level of the new shaft for ventilation. Reservoirs of the company's property are being made at this time, and it is supposed that a division into two or more companies is contemplated.

One east of the Sierra Nevada new shaft and in the vicinity of the cemetery, a modest structure denotes the position of the North Consolidated Virginia. It would hardly attract the attention of the visitor who takes note of the elaborate and extensive buildings of the more developed mines, but knowing observers find it worthy of close observation. This was originally two claims, the Spring Garden and the Butcher. The south half was located in 1860, and the north in 1874. In January, 1875, the present company was incorporated in California, with a capital stock of \$10,000,000 divided into 100,000 shares. The officers at present are R. C. Rogers, President; James Maguire, Secretary; D. H. Jackson, Superintendent. Annual meeting, first Monday in February. The north half of this claim is east of the Sierra Nevada, and the south half east of Mexican and Union Consolidated, the south boundary being nearly identical with the north line of the Ophir. The shaft is 1,700 feet from the eastern shaft of Sierra Nevada. It has three compartments, is well timbered and fitted with the most improved hoisting apparatus. The work of sinking the shaft has been prosecuted with the steady purpose of reaching a depth of 1,000 feet before drifting, successfully resisting the temptation to spend money on explorations at lesser depths which would probably result only in gratifying an expensive curiosity. The present depth is 900 feet, and sinking continues with all the speed consistent with economy. At 500 feet the first quartz stratum was found, and several others have been passed through since, varying from six inches to six feet. Most of this was low grade ore—some of it assaying as high as \$17. At the present depth the shaft is passing through quartz, clay and porphyry—the quartz beginning to predominate and exhibiting a clearer and livelier appearance. A double engine, with a capacity for 1,500 feet, does

the hoisting and has hitherto lifted the water; but the excavations are now being made for a pumping engine, which, with its appliances, will be the largest and heaviest now in use in the district, and will only be exceeded by the huge machinery which is about to be used at the Savage and some one or two other mines. Hitherto this water, to the extent of 14,000 gallons in 24 hours, has been handled without interfering with other work by the following ingenious method: At every 200 feet tanks were built, into which the water was conducted, and here it was retained until other work permitted it to be removed. This was done rapidly by means of an iron bucket holding 300 gallons, which was let down and filled from each of the tanks in succession. It is the special claim of this company that the results of their operations are largely above the average in proportion to whole amount of their expenditure. Two assessments have been made, aggregating 75 cents to the share, and up to May 1st the total expenditure was \$64,363.54. The proportion which this outlay bears to the development of the mine may be readily calculated from this account of their operations.

In the opposite direction from the Sierra Nevada, that is, nearly due west, and extending from the base up the side of Cedar hill, is found the ground of the Jacob Little Consolidated company. This is a consolidation of three other old claims with the original Jacob Little, which were the Norton, Bowen and Manhatian. The latter were worked for twelve years, principally by tunnels running into the hill, and at times yielded fair paying ore, which usually contained a large percentage of gold. The consolidation and incorporation was in January, 1875, with capital stock of \$10,000,000 and 100,000 shares. After the consolidation the work was continued by tunneling, the main tunnel running well under the hill, to a distance of over 200 feet. From this drifts were run at various angles, and the northwest drift carried about 200 feet with good prospects of resching pay ore. This was the condition of things in November, 1875, when work was suspended. Since that time nothing has been done, but preparations are now being made to resume at an early date.

There are many other Cedar hill claims upon which more or less work has been done; some of it in earlier times and some more recently, but none with any notable development. The Iowa, Lincoln and Peytona may be named in this class; the last mentioned being the only one upon which any work is being done at present.

The encouraging outlook for the past few weeks all along the Comstock has received no check since my last letter. Everything is bright and full of promise, and some of the developments are striking, but as yet these can only be whispered. An immense amount of work is being done at the mines that are preparing for new and heavier machinery. At the California pan mill the new reservoir is completed, and they are now replacing the old engine by a new one. At the C. C. shaft the engine is being altered from a high to a low pressure. At the Hale & Norcross, the Gould & Curry and the Savage, great numbers of extra men are employed in preparing for and putting up the new pumping machinery. The necessity for retimbering a portion of this 1500-foot level of the Consolidated Virginia has not interfered materially with hoisting ore, and this daily yield is not prospectively lessened. The new superintendent of the Consolidated Virginia and California assay office is Wm. T. Reilly, late assistant assayer in the San Francisco mint.

Virginia, Nevada, May 25th.

Gold-Bearing Slate.

We examined this week some specimens of gold-bearing slate from the Old Hickory mine in El Dorado county. This mine is situated on the North fork of the American river, about 2½ miles from Placerville. The vein is gold-bearing talco-slate, 10 feet wide, and is traceable for miles. There is no quartz in it at all.

The assays from this ledge run, from actual working test, from \$50 to \$100 per ton, but there are several tons on hand mining over \$2,000 per ton. The deposit is quite large. The ledge has been known for a long time, but after it was discovered to hold gold it never paid, owing to the difficulty of working it in the batteries. The gold being evidently covered with a thin film of talco-slate, passes easily over the plates and does not amalgamate. This little film is acted on successfully by an alkali.

The ore is quite peculiar and carries a good deal of sulphurets, besides the free gold. The walls of the vein are perfectly smooth and well formed. It is on a slate formation, but of a different character, of course, from the country rock. A vein of this kind is now being worked with profit in South America, although it is something new here.

The mine has recently been incorporated here by the following gentlemen: E. D. Sawyer (Treasurer), S. F. Shepley (President), A. E. Ball (Secretary), R. P. Clement and E. G. Gaertner. The shaft on the mine is now down 75 feet, and reduction works are now being made to put on the mine. There are several of these slate ledges through the country, but whether others of them are gold bearing or not we do not know.

NECESSARILY DEFERRED.—We have on hand a valuable article—a review of the Mindleff process—which was received too late for this issue. It will appear in the Press of next week.

[Editorial Correspondence.]

The Centennial at Philadelphia.

The Grand Opening.

The inauguration of the great American Centennial exposition, commemorative of the hundredth year of our national existence, is now an accomplished fact. Everything connected with this "opening day" went off as per programme. The President, most of the leading dignitaries of the land, and all the foreign representatives at Washington were present to aid and give dignity and importance to the event. The great American Empire of Brazil was represented by the personal presence of her wise and popular sovereign and his suite. The Emperor preceded the President in his arrival upon the stand, and when the latter arrived, and in the presence of the vast waiting multitudes extended the hand of friendship and recognition to his brother ruler, the shout which went up gave unmistakable evidence of the warmth of friendship and sympathy which exists between the two great leading nations of the American Continent.

The telegraph has informed the world of all the leading incidents of this occasion, and has, no doubt, told the readers of the Press how the dignitaries who were present, immediately after the conclusion of the speaking and singing, passed hastily to machinery hall, where the President, with his own hands, started the great Corliss steam engine, by which the fourteen acres of machinery in that building was set in all its varied and complicated motions. The exposition was, by that crowning act, fully inaugurated and put into practical operation.

Four Days After.

The exposition has now been four days in operation, and the sound of the hammer and the saw is still going on in all directions. In the fortissimo part, the music in the main exhibition room—by Gilmore's band—has decidedly the beat of it; but when it comes down to the low, sweet solos of the cornet or flute, the noise of the artisans at their work is in the ascendant. Trains of cars are constantly arriving, loaded with goods which have been delayed. No less than 50 loaded cars entered the grounds on Thursday, and large numbers arrived on Friday and Saturday. Goods are also arriving by steamers and sailing vessels, and being transferred to the grounds by trucks. It will be many days—some weeks indeed—before all the exhibits are in. It is doubtful if everything will be in perfect order before the fourth of July—the great anniversary day itself.

Still, all except the exhibitors themselves are more than satisfied with the progress which has been made. The display in the various buildings is extremely gratifying. In the main exhibition building, although many sections are still almost bare, or in great confusion, nevertheless the show is extremely rich and elaborate. Nothing ever before seen in this country will bear any reasonable comparison with the richness, taste and variety of the display. Philadelphia compared with London, Paris and Vienna.

Your correspondent has thus far endeavored to employ his time to the best advantage in securing a general idea of the exhibition throughout, with the view of being able to institute some comparison between its extent and that of other similar exhibitions abroad. London, Paris and Vienna have each had their turn, and the two former have repeated their first efforts—London once, Paris twice. A comparison of the statistics of those exhibitions shows favorably for Philadelphia—as far as area of exhibition space is concerned; and so far as your correspondent can learn from those who were present at the various European exhibitions the same advantage holds good in other respects also. The first great world's fair was held in London in 1851. We append a statement of the exhibition area of that and the subsequent European exhibitions, stated in acres and tenths of acres as follows:

England's World's Fair of 1851.....	18.6	acres
Paris " " 1855.....	22.1	"
London " " 1861.....	23.9	"
London " " 1871.....	26.6	"
Paris " " 1867.....	31.0	"
Vienna " " 1874.....	56.5	"
Philadelphia Centennial 1876.....	60.0	"

The Philadelphia Centennial exhibition area is made up as follows:

Main Exhibition Building.....	21.5	acres
Memorial Hall or Art Gallery.....	2.5	"
Machinery Hall.....	14.0	"
Horticultural Hall.....	2.0	"
Agricultural Building.....	10.0	"
U. S. Government Building.....	2.0	"

Total.....62.0 acres

The balance—eight acres—needed to bring up the area to the figure of 60 acres, as given in the first above table, is made up as follows:

The Nevada State building, in which a complete five-stamp quartz mill is shown in operation; a large building, erected by Gillinder & Sons, of Philadelphia, in which is shown the whole process of glass manufacture, melting, blowing, pressing, cutting, etc., with a large display of manufactured ware; the Women's pavilion, devoted to the exhibition of the handiwork of the women of the United States; an extensive building devoted exclusively to the practice and display of the photographic art; a

large building devoted exclusively to the exhibition of osriages, wagons, etc.; also several other minor show buildings, to say nothing of a large amount of open area occupied by the U. S. Government for the display of military field equipments, the field telegraph, etc., which may properly be shown in the open air. These will more than bring up the floor space of this Philadelphia exposition to 60 acres—three and a half acres more than the largest European display, at Vienna, in 1874.

We may in very deed pronounce the exhibition a wonderful success—a real triumph for America. The managers of the exhibition, the people of the State of Pennsylvania, and especially of this city of Philadelphia, may well congratulate themselves that the energy, power and steady endurance which they have manifested during the past two years, against much indifference and all manner of hindrance and even opposition, has at last resulted in a most glorious triumph—a triumph of which the nation may well feel proud, a success which is recorded by the lips of thousands of representative people from every nation on this globe, who are here present to see and report in person.

It is now fully demonstrated that the American Centennial exhibition will prove the grandest collection of the products of human industry, art and taste which has ever been presented to the world. Let us hope, also, that it will prove equally successful as a pecuniary enterprise. If it fails in that particular it will be because the American people cannot or will not appreciate and properly patronize an effort which is eminently worthy of their patronage, and which is capable, by comparing the achievements of our people with those of others, of teaching everything in the way of human handicraft which is useful to learn, or which man, from observation and study, can so attain.

The Centennial Grounds.

Fairmount park, the site of the Centennial grounds, is well known to all who are ac-

SCENE IN TAHITI.

of its form and topography may be learned from the diagram given in the issue of the Press of April 29th. The area is triangular in shape. The distance from one point of the triangle to each of the others is about one mile in a direct line, and considerably over that by following the avenues and paths necessary to be traversed to reach the several points. The main entrance is approached from the city, along Elm avenue, by most of the city street cars, and also by the Pennsylvania Central railroad. The cars of the latter pass their freight trains directly into the grounds, as seen by the diagram aforesaid, between the two offices.

The grounds are entered by 13 different gates, each of which is supplied with a greater or less number of self-registering turnstiles—one entrance, probably, for each of the original 13 States. Only a portion of the entrances are painted in Philadelphia. The portion enclosed comprises about 260 acres. Some idea shown in our diagram. The main exhibition buildings are six in number, and cover, according to the table already given, an aggregate area of over 50 acres. These are supplemented by several other large and pretentious show buildings, some of which have already been mentioned. The total number of buildings within the enclosure is set down at 150, to which others are still being added. The larger number consists of the various State buildings, restaurants, beer and liquor saloons, newspaper offices, etc.

Magnificent Distances.

By further reference to the diagram, and reflection upon the distances and areas given, it will readily be realized that, as an exhibition ground, it is divided by magnificent distances as well as covered with mammoth structures. The nearest practicable distance between the main exhibition building or the machinery building, and the agricultural building, is about half a mile. The Government exhibition building and horticultural hall are also nearly as distant from those mentioned and from each other. Hence a large amount of walking is requisite to simply make the round from one building to another during a single day, to say nothing of treading the avenues and aisles of each separate building. Of these there are 11 miles in the main exhibition building alone.

Conveniences for Getting About.

For the convenience of getting about, a narrow gauge railroad track has been laid, following, as close as possible, a course just inside of the enclosure. By taking the cars upon this track a person may readily pass from one portion of the grounds to another for 10 cents. As a further convenience for getting through the main thoroughfares of the grounds and buildings, a large number, several hundred, of rolling chairs have been provided and stationed at intervals all through the grounds and in the main buildings, which can be hired for 60 cents an hour, or with a large reduction for a longer time, upon which a gentleman or lady can be seated and trundled wherever they may wish. By this means the tired visitor, or even an invalid, may take a leisurely view of the exposition, without the tediousness of personal locomotion, leaving their seat at any time when they desire to take a more close view of any particular object than can be obtained from the chair. One of these chairs can be hired the entire day for four dollars. For the further convenience of visitors, restaurants, beer stands, booths and dairy stands, etc., are placed at close intervals all through the grounds and buildings. Soda, meat, milk, etc., can be had at their proper stands. Pans cold water can also be had now and then from living fountains, so placed as to interfere as little as possible with the profits of the beer sellers. The prices of everything inside the gates is just about double that at the restaurants and saloons outside, on which account the latter appear to be liberally patronized by those who find it necessary to be economical and don't feel like filling their pockets with luncheon from home. Checks are furnished to all who desire to leave the grounds for a short time, good only for that day.

The State Buildings.

Referring once more to our diagram, the most of the various State buildings are ranged along and fronting the winding avenue which

Whitehill of Nevada, Mr. J. P. Woolman, commissioner from Montana, and Mr. Thos. Donaldson, commissioner from Idaho, are in place but not yet labeled, and make a fine show. They will be more fully described in a future letter. These exhibits are in the Government building, adjoining the Smithsonian Exhibition under charge of Prof. William P. Blake, formerly of California.

Mr. J. R. Scapham, in charge of the Central Pacific railroad's California products, curiosities, etc., is fast getting his exhibition into shape. One carload was still to arrive on Saturday.

Mr. Schuman of Woodward's gardens is here, but has not yet got his cases fitted up.

Among other exhibits which I have casually noticed in passing through the building, are photographic portraits from Bradley & Rulofson, Yosemite views from Watkins, portraits from Taber and from Weston, Central American views from Maybridge, and stereoscopic views from Riley.

Gustave Mahe, Kohler & Frohling, M. Keller & Co., exhibit wines. The big California grapevins is here, but no acceptable place has yet been assigned for it. The section of bark from the Big Tree has been set up near the grounds as an outside show.

Judges from the Pacific Coast.

I have just learned that the following persons from California have been appointed as Judges: Irving M. Scott, of San Francisco, on machine tools for iron, wood and stone; J. D. Hagne, San Francisco, on mining and metals; George W. Henston, on India rubber products and goods; Gen. H. M. Naglee, San Jose, on wines; James Bruce, Corvallis, Oregon, on agricultural machinery.

Goods are still coming. A train of seven carloads is now standing on the track near the Press headquarters, where I write. W. B. E. Centennial Grounds, May 15th.

One of Our Notabilities Gone.

Papers all over this State and Nevada have given due notice of the death of one of our notable characters, John A. Thompson, known all over the Pacific coast as "Snowshoe Thompson." He died on Monday of last week at his ranch in Diamond valley, Alpine county, in this State. In the early days of California and Nevada he achieved considerable notoriety as a carrier of the mails between Placerville and Carson valley on snowshoes.

His great natural advantages, physical power, fitness and endurance, were supplemented by a habit of punctuality which made his name as dear as well as familiar in the mouths of the people of this coast as household words. He was born at Upper Tina, Prestigard, Norway, in 1827, which makes him 50 years old at his death. In 1837 he came with his father to the United States, settling in Illinois. Four years later he came across the plains to California, making Placerville his stopping place. His first trip over the Sierras was in 1856. He went from Carson valley, a distance of 90 miles, carrying the mail bags strapped upon his back, the snow lying in some places 50 feet deep; but he made a successful trip over this sea of snow on his long Norwegian snowshoes. He continued to carry the mails between these points all that winter. Several years since he acquired a ranch in Diamond valley, where he resided until his death. The Carson News thus notices his funeral:

"The remains were brought to Genoa Thursday afternoon for interment, followed by a large procession of mourning friends in carriages and horseback. Many of our citizens proceeded up the valley and met the procession. Funeral services were celebrated in the court-house, under the direction of Dr. Killpatrick. Dr. Smith informs us that the deceased was carried off with inflammation of the stomach and bowels, with which he had been afflicted some two months, though the disease had not prostrated him only about eight days."

Tahiti.

We give on this page a pretty scene from Tahiti. As the island is just now filling our markets with its fruits, it will be interesting to our fruit growers and consumers to catch a glimpse of the land whence the fruit comes. An enthusiastic French traveler, writing of the scenes which we illustrate, says:

"The appearance of the shores of Tahiti offers a grand variety of natural beauties. A happy combination of land and water, of precipices, of plains, of trees reflecting the thick foliage upon the limpid waters, of lofty mountains delineating their profiles on the clear sky, gives to the spectator delightful sensations. Thousands of trees produce excellent fruit, which only demand that a man put out his hand to gather them. The landscape is pleasing with the shade of orange and citron trees." We doubt not since the day when the writer visited the island the Tahitians have learned from their commerce that fruit is too valuable to bang where any one could put hand to it, but we have good evidence of the choice fertility of the soil and the bearing of the trees from the stores which ships are almost daily unloading at our wharves.

The Pacific Coast Exhibits are fast assuming shape. The mineral exhibits from California, Nevada, Montana, Idaho, Oregon and Arizona, under charge of Dr. H. R.

On Sunday evening there were violent storms at various points in the Middle and Western States.

PACIFIC MACHINERY DEPOT,

H. P. GREGORY & Co., Nos. 14 & 16 First Street,

San Francisco, Cal.

San Francisco.

Are the only Agents for sale of these
Levi's in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)
Our new Mining Engine is built from plans and specifications of several of our most successful MINING ENGINEERS, and the result is the most complete
Double Drum Hoisting Engine
Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

And in accordance with law, and an order of the

Board of Directors, made on the third day of April,

1876, so many shares of each parcel of said stock as

may be necessary, will be sold at public auction, at the

office of the Company, 507 Montgomery street, at San

Francisco, California, on Monday, the fifth day

of June, 1876, at the hour of one o'clock, P. M., of said

day, to pay said delinquent assessments thereon, to-
gether with costs of advertising and expenses of the
sale.

F. E. LUTY, Secretary.

Office, 507 Montgomery street, San Francisco, Cal.

Mariposa Land and Mining Company

Location of principal place of business, San Francisco,
Cal. Location of works, Mariposa

County, Cal.

Notice is hereby given, that at a meeting of the Board of
Directors, held on the second day of May, 1876, an assess-
ment (No. 5) of one dollar per share was levied upon the
capital stock of the corporation, payable immediately, in
United States currency, to the Secretary, at the office of
the company, No. 309 Montgomery street, room 33, Nevada
Block, San Francisco, Cal., or to the Assistant Secretary,
at the office, No. 8 Nassau street, New York.Any stock upon which this assessment shall remain un-
paid on the third day of June, 1876, will be delinquent, and
advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Friday, the 30th day
of June, 1876, to pay the delinquent assessment, together
with costs of advertising and expenses of sale. By order of
the Board of Directors. LEANDER LEAVITT, Secretary.Office, Room 33 Nevada Block, No. 309 Montgomery
street, San Francisco, Cal.

Taylor Mill and Mining Company.—Prin-

cipal place of business, City and County of San Fran-
cisco, Cal. Location of works, Garden Valley Mining
District.Notice is hereby given that at a meeting of the Board of
Directors, held on the fifteenth day of May, 1876, an as-
sessment of twenty (20) cents per share was levied upon
the capital stock of the corporation, payable immediately
in United States gold and silver coin, to the Secretary at
his office, 601 Montgomery street, San Francisco, Cal.Any stock upon which this assessment shall remain un-
paid on the twenty-first day of June, 1876, will be delinquent,
and advertised for sale at public auction, and unless pay-
ment is made before, will be sold on Thursday, the sixth
day of July, 1876, to pay the delinquent assessment, to-
gether with costs of advertising and expenses of sale.

SAMUEL S. MURPHY, Secretary.

Office, 601 Montgomery street, San Francisco, Cal.

THE MINING AND SCIENTIFIC

PRESS PATENT AGENCY was estab-

lished in 1860—the first west of

the Rocky Mountains. It has

kept step with the rapid march

of mechanical improvements.

The records in its archives, its

constantly increasing library, the

accumulation of information of

special importance to our home

inventors, and the experience of

its proprietors in an extensive and

long continued personal practice

in patent business, affords them

combined advantages greater

than any other agents can possi-

bly offer to Pacific Coast inven-

tors. Circulars of advice, free.

**Schofield's
SULPHURET CONCENTRATOR.**

THE BEST MACHINE IN USE FOR
 SAVING SULPHURETS.

No Power Required to Run it, and only a Small Stream of
 Water under a Light Pressure.

ECONOMICAL,
 EFFECTIVE,
 DURABLE,
 AND SURE IN OPERATION.

The especial attention of parties erecting new mills is called to this
 Valuable Improvement.

WE GUARANTEE THAT THIS MACHINE WILL SAVE NINETY PER CENT. OF ALL THE SULPHURETS
 IN THE ROCK AT A MERELY NOMINAL EXPENSE. IT HAS NOW STOOD THE SEVERE
 PRACTICAL TESTS OF OVER A YEAR'S WORK AT DIFFERENT MILLS
 ON THIS COAST, AND HAS BEEN EMINENTLY
 SUCCESSFUL IN EVERY CASE.

The following letters, from practical men who have used this machine, will show to
 those interested what it has accomplished:

BANDERETA MINE,
 Mariposa County, Feb. 7th, 1876.

CHAS. SCHOFIELD, Esq.—Dear Sir: We have been using your Concentrator at our mill
 about six months, and find that it saves over 90 per cent. of the sulphurets contained in the ore,
 and all of the amalgam and quicksilver which escapes from the battery. The machine is simple
 in construction, perfect in operation, and requiring no power to run it, is very economical. I
 can confidently recommend it to all mill men as the best and cheapest Ore Concentrator now in
 use.
 Yours respectfully, LEVI NOEYS, Superintendent.

NONPAREIL GOLD MINING CO.'S WORKS,
 Deer Flat, Tuolumne County, Cal., April 12th, 1876.

MR. CHARLES SCHOFIELD—Dear Sir: It is four months since the Sulphuret Concentrator
 you furnished our company's mill with was first put in operation, and during the past three
 months has been nearly in constant use. The men attending the Concentrator having acquired
 by practice a thorough knowledge of its workings, there is nothing more to be desired; it is
 perfect. A number of mill men have examined the Concentrator and its workings, and pro-
 nounce it the most simple in its construction, perfect in its work, and cheaply run of any they
 had seen. If you think by showing this it will assist you in disposing of your Sulphuret Con-
 centrators, you are at liberty so to do, as it will afford me much pleasure in having contributed
 my little mite towards rewarding true merit. Hoping you will meet with complete success,
 I remain yours truly,
 JOS. J. DOPRAT, Superintendent.

CON. ALABAMA M. CO.,
 Tuolumne County, May 1st, 1876.

C. SCHOFIELD, Esq.—Dear Sir: The Concentrating Machine recently purchased of you is
 now in active operation, and we are highly pleased with it. It saves over 90 per cent. of our
 sulphurets, and is run with very little expense. We could not afford to be without it, and can
 safely recommend it to all mill men as the best and most economical machine in use.
 M. S. MCCONNELL, Superintendent.

WASHINGTON MINE,
 Mariposa County, Cal.

CHAS. SCHOFIELD, Esq.—Dear Sir: Having had one of your Double Rigged Concentrators
 in use now at this Mill for over a year, I take this opportunity of informing you that it is far
 superior to the old English Buddle we have been using for the last four years, not only in a
 saving of labor, but having a less waste of sulphurets in washing.

We have the machine connected with the tail sluice, and receives the sand and water direct
 from the batteries, without any handling, and it does the concentration for the 20 stamps easy,
 with a loss of less than 10 per cent.

Two Chinamen do all the work required—one night and the other day—working 12 hours
 each, and get out about a ton each day, thus concentrating 30 tons into one, at a cost of less than
 four dollars. As the cheapest, most economical and best working Concentrator I know of I can
 recommend it to others without any hesitation.

Yours truly, GEO. E. WEBBER, Jr.,
 Superintendent Washington Mining Company.

MR. SCHOFIELD—Dear Sir: Having carefully examined your Concentrator, which I have
 seen in successful operation at the Francis Company's Mill and also at the Benton Mills, on
 the Mariposa Estate. I have no hesitation in saying that it is the most valuable Concentrator
 I have met with during my long experience as amalgamator in this country. Its manner of
 catching quicksilver and amalgam is thorough and complete, and it saves the sulphurets clean
 and with a loss of less than ten per cent.
 Yours respectfully, L. BURDOW.

MR. C. SCHOFIELD—Sir: I have worked one of your Sulphuret Machines at the Benton
 Mills about 30 days, and am satisfied it is the best machine for saving amalgam and sulphurets
 ever used on the Mariposa Estate.
 L. GILMAN.

The following testimonial is from the well known mining expert, PROF. J. E. CLAYTON:

CHAS. SCHOFIELD, Esq.—Dear Sir: Having followed the business of mining engineering
 for upwards of 30 years, and having had in this connection much to do with regulating machi-
 nery for saving gold and concentrating sulphurets, and having in nearly every mining camp
 on the Pacific Coast examined the various kinds of Ore Concentrators in use, I will say that I
 have nowhere seen anything half as cheap and simple in its construction, scientific in principle
 or effective in operation as your machine.
 J. E. CLAYTON.

Machines can be Furnished at Short Notice. In all Cases we Furnish the
 Concentrator Complete, Set it Up, and Instruct the Buyers as to
 the Proper Way of Managing It.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING

THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS

ON THE LEGS OF TRIPOD, ARE ALL IMPROVED

AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never fails of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

BEFORE PAINTING YOUR HOUSES

Send for Sample Card and Circular and Carefully Examine the

AVERILL CHEMICAL PAINT,

MIXED READY FOR USE.

This Paint is prepared in liquid form, READY FOR THE BRUSH. It requires no addition of oil or spirits. It is composed of the best materials known to the trade—Pure Linseed Oil, Strictly Pure White Lead, Pure Zinc, and the finest of coloring matter for tinting. It is the BEST, CHEAPEST, MOST DURABLE AND BEAUTIFUL PAINT IN THE WORLD. Is just what is wanted by every farmer, mechanic and everybody who has a house, fence, barn, or wagon to paint. Requires no skilled labor, as any one can apply it who can handle a brush. It is put up in cans of any required size, from a quart to five gallons, and is sold BY THE GALLON. It gives a firm, elastic and brilliant glossy finish, and will neither crack, peel or wash off, like most paint in common use, but is proof against rainstorms and all action of the elements. Buildings painted with this paint five years ago look fresh and like new to-day and will need no more paint for years. Of no other paint can this be said and proved.

The Averill Chemical Paint Company supply a long-felt want. They not only furnish a Paint more lasting, handsomer, and at the same time cheaper than the best of others, but it is in a liquid form—white and all the fashionable and most exquisite shades—ready for the brush. So that farmers, in fact everybody, can be their own painter if necessary. Indeed, all the buildings upon which the Averill Chemical Paint has been applied, are marvels of beauty.—*Christian Union*.

We know of no subject of such importance to householders as that of a good, handsome, durable paint for their dwellings. Within the past few years we have watched the progress of the Averill Chemical Paint and have had frequent opportunities to test it fully. We think it just the article to supply the need, and give it our hearty endorsement.—*N. Y. Independent*.

From the Thousands of Testimonials sent us, we select the following, which we present for your careful consideration:

A PAINT FOR FARMERS.—Prof. J. B. Turner, Jacksonville, Ill., is a man of great practical knowledge and experience; hence, we attach a great deal of value to the following, from his pen, which we find in the *Prairie Farmer*.

"Some two years ago I sent for and got from a barrel to a harral and a half of Averill Chemical Paint, of light dun color, which I thought would suit me well enough for all work—houses, doors, blinds, fences, bee-hives, wagons, tons and all. I put two coats upon my residence here, and run over three or four of my smaller farm houses on my farms. With what was left I painted my bee-hives, wagons, wheelbarrows, rollers, harrows, fences, etc., etc., and on all these buildings, implements, tools, gates, etc., the paint is as hard and glossy to-day, as far as I can see, as it was a month after it was put on, and bids fair to hold its own at least for five years to come, (if not ten of them,) better than ordinary white lead and oil does for even two years.

"I have watched it now for about two years with interest and care, and have never found a single spot where it peeled, cracked, or chalked off, as our other paints do. Others who have used this paint like it equally as well. But the point is, I can take one and the same keg and brush, and go over all my buildings, wagons and tools, with no needless waste of paint, brushes or time. It is quite as good for inside finish, as it leaves a coat that shines and washes like glass."—*Moore's Rural New Yorker*.

THE AVERILL PAINTS.—In reply to some inquiries of our readers, we would state that we have given these paints, prepared by the Averill Chemical Paint Company, a full trial, and they appear to possess all that is claimed for them: spreading easily, adhering well, drying soon, and imparting handsome shades of color to the surface covered. Farmers and others who do their own painting, may avail themselves of the convenience of purchasing these paints, of any desired shade, already mixed for use, at a very reasonable price.—*Cultivator and Country Gentleman*.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your letter I have to state that for more than six years I have dealt in and used your paint. I have during that time carefully observed its application and use, and from practical knowledge can certify to its unrivalled excellence. During my six years' acquaintance with it, there has not come in my knowledge a single instance of failure in any case where it has been used. All to whom I have supplied it unite in commending it for its superior claims over all other paints now in use. The Averill Paint externally used, or, in other words, exposed to the action of the weather, neither rubs off nor changes color, as do other paints, and will retain its freshness and adhesive property for years. Pure lead and oil will in a short time become dry, and are easily rubbed off, the loss of oil leaves the lead in a dry, oxidized state. As a matter of economy the claims of the Averill Chemical Paint to popular appreciation and general use are beyond question. A house properly painted with it once will be better preserved, and present a neater appearance at the expiration of seven years, than it would if twice coated with lead and oil paints now in use. There can be no question, then, that to use it is both labor-saving and economical. So well assured and convinced am I of its established right to this distinction over all kinds, that had I fifty houses of my own to be painted, the "Averill" alone should be my choice and used.

Yours, very truly,

S. J. ALDEN, Druggist.

UNIVERSITY OF CALIFORNIA, BERKELEY, August 16, 1875.

TO THE CALIFORNIA CHEMICAL PAINT CO. Gentlemen—In reply to your note of the 13th inst., I willingly state that the work done by you in painting the exterior of the North Hall or College of Letters is in every way satisfactory, and the appearance of the building since it was painted excites the favorable comment of all who have seen it. As I have had occasion to use the Averill Paint before, my experience has been such that I prefer it to any and all others when properly applied. I am very truly yours,

ROBT. E. C. STEARNS.

PATENTEE AND BUILDER OF THE

BEST PORTABLE STRAW OR WOOD BURNING THRESHER ENGINES, 1876.
Send for Testimonials and Price to

JOSEPH ENRIGHT, San Jose, Cal.

Ms. J. ENRIGHT—Dear Sir: The Straw Burning Engine I bought of you, and which was used in Yolo county, has given me perfect satisfaction. It is everything you represented. We have had no difficulty in generating all the steam required, and the amount of straw consumed can hardly be misused. We find it much safer, on account of fire, than a wood burner. Many persons, both threshers and farmers, have come to see it run, and all express themselves highly pleased. The opinion of all was, that it is just what we need, being safe and economical.
H. M. LARUE.

Umpire Tunnel and Mining Company of Utah.

At a Directors' meeting of above company, held on the 16th inst., it was resolved that a meeting of stockholders of the company be convened on Monday, June 19th, 1876, at the office of the company, 535 California street, to decide upon a proposition to increase the capital stock of the company from three hundred thousand (\$300,000) dollars, divided into thirty thousand (30,000) shares of ten (10) dollars each, to seven hundred and fifty thousand (\$750,000) dollars, divided into seventy-five thousand (75,000) shares of ten (10) dollars each.

Some of the Mines of El Dorado County.

[By Our Own Correspondent.]

Before reaching Placerville I had almost come to the conclusion that the people of that county had lost all interest in their mines, more particularly their quartz claims. In this I was mistaken. Work has already commenced on some lodes that had not been worked for some time, and there seems now to be a disposition to commence operations within the next two months on many an idle claim. In fact, the Fryer process and other new methods of reducing ores are reviving hope in the breasts of many from the promise of success which they give, and soon I hope you will hear of a general awakening in this heuhtened land on the subject of mining.

Some rich discoveries have been made here within the past two years in what is called "porphyry claims." I have made a cursory examination of three or four of them. The lode is chiefly of porphyry, and has well defined east and west walls.

Quartz, however, is evidently the matrix of the gold, and it is probable that by sinking to considerable depth on them the quartz seams, which are from one to six inches in width, would be found much larger, developing, in some cases, into a regular quartz lode; for as to those examined, the porphyry within the walls appears to be a metamorphosed slate, and it is likely the change in the rock has taken place about the time the gold was deposited, and produced by similar causes. No two have precisely the same characteristics. For example, in Mr. Shaw's claim, near El Dorado, a small seam of quartz, mostly decomposed, is found on the east and west walls 3 to 4 in. wide, and wherever there is an elbow the chimney of rich ore appears—the hanging wall carrying the largest deposits. A pocket not larger than an upright churn has yielded from \$3,000 to \$8,000. Mr. Shaw told me that two or three men had taken out here \$33,000 the past two years. They often work for months without finding anything.

In Mr. Brown's claim the quartz vein is sometimes six inches in width, and runs in the midst of the porphyry instead of along the walls. The lode, 100 feet wide, is bounded on one side by slate, and on the other by granite, the gold being more evenly distributed, and not found in from two to five pound lumps, as in the former case, the largest being about \$200. Thus far his labor has been handsomely rewarded. The figures are withheld from the public by his request. In this connection it might be well to state that many in this county, as in other places, are quietly working away at their claims and are doing well, but prefer not to have their private affairs paraded before the public.

In the same neighborhood is a very promising quartz vein, opened to the depth of about 20 feet, running northeasterly, near the junction of the slate and granite, belonging to the Messrs. Miller—known as the Miller claim. Lode from two to three feet wide, assays have run as high as \$1,000—learned that it had worked by mill process about \$15 per ton. From what I could learn it is not a pocket lode; the gold in seams is fine and somewhat evenly distributed. Mr. N. S. Miller, one of the partners in the mine, is now prospecting or working, not far distant from this, another quartz lead, which was not visited. Mr. M. will pardon me for stating what his neighbors all around seemed to know, that he was one of the lucky ones that recently struck a rich pocket in a porphyry claim, that made him in a few hours a richer man by several thousand dollars (they say \$7,000 or \$8,000). The rock was pounded in this case as in all similar workings, in a common hand mortar.

The Davidson mill and quartz mine in the same neighborhood are expected to start up some time this season. The mill has 20 stamps and the shaft is down 300 feet. The

Church Union

Gold mine, two and one half miles northeast

of El Dorado, consists of two lodes, the Union and Cosmunes, shaft 275 feet on each. The books of this company show that \$1,000,000 has been taken from the Union lode since 1851. The ore pays \$35 to \$40 per ton. The mill is now running on Cosmunes ore. Last crushing \$18 per ton, 10-stamp mill, capacity 15 tons per 24 hours. Run by water, hydraulic pressure, hurdy-gurdy wheel, 400 feet pressure,

in the county. The company are pushing the work rapidly, working at present with an arrastra, and are intending, at no distant day, to put up a mill.

The St. Louis Gold Quartz Company, Six miles east of Placerville, lays claim to having the finest hoisting works in the county. Their incline—three compartments—is down 220 feet, and thoroughly timbered. Width of

FIG. 1. GOVERNOR AND VALVE.

20 inches of water, weight of stamps 650 pounds, 18 men employed. Indebted to Mr. D. C. Wickham, superintendent, for facts.

The Schneider claim, one and a half miles south of Diamond Springs, embraces two lodes, averaging each three feet; rock works from \$20 to \$30 per ton by arrastra. The quartz has a lively appearance, with gold to be seen in many specimens. At work; about 150 tons of

lode, four feet; the character of the rock is considered very good, a high grade ore, assaying well. It is said that gold is found in paying quantities, even in the porphyry. There is a considerable quantity of ore on the dump, but no mill has been put up, from the fact that the superintendent, an old quartz miner (and by the way, an acquaintance of former times in Virginia City), thought it advisable to first

FIG. 2. SECTION OF GOVERNOR.

FIG. 3. FOR VARIABLE CUT-OFF ENGINE.

ore on dump. Tunnel 300 feet in length; depth of shaft, 50 feet. Can be tapped by tunnel to the depth of 400 feet. Located on Martheus creek; has free water six months in the year, and can get 300 to 400 feet pressure by purchasing water. The greatest depth reached 140 feet—tapped by tunnel.

The Veach Quartz Mining Company

Is situated near old Baltic mill, 21 miles east of Placerville, on Camp creek, or north fork of Cosmunes river. The discovery was made July last. The lode is about two feet in width; tunnel 30 feet and shaft 40 feet. Mr. Veach, the locator, informs me that the ore will average \$30 per ton, gold very fine and interspersed evenly through the quartz, and expressed the belief that it bids fair to prove one of the best

prospect the mine thoroughly. In this he was wise, for many a mill has been built before it was required. My modest friend believes that depth only is required to place this mine on a solid paying basis. It is owned chiefly by parties in St. Louis, Mo., as its name indicates. Placerville, May 24th. K.

DEVELOP THE MINES.—This matter is brought before the readers of the *Placer Herald* in the following brief and pointed manner: "The importance of developing our mining interests cannot be overestimated. Activity among miners promotes business, and business leads to wealth; inactivity promotes dullness, and dullness begets hard times."

The Allen Governor.

During the last fifty years it has been the constant effort of thoughtful engineers and machinists in all the world to discover the best mode of maintaining a uniform speed in the working of steam engines while variations occur in the amount of work done by them. It is well known that machinery cannot produce its most profitable results without being run at the highest rate of speed consistent with its durability and the production of a perfect fabric, and that no machinery can be run at or near its highest rate when subjected to uncontrolled variations. The object sought for in the peculiar construction of the Allen governor, illustrated on this page, is the thorough and accurate regulation of steam engines, and especially those with adjustable cut-off.

The peculiar construction of this governor will be clearly understood from the following: "Within a corrugated cylinder, which has small projecting ribs on its interior periphery, and which is partially filled with oil, a paddle-wheel is caused to revolve by a spindle passing through one end of the cylinder, driven by a belt communicating with the fly-wheel shaft. The tendency of the revolving paddle-wheel is to cause the cylinder to move in the same direction. On the opposite side of the revolving spindle is a trunnion or short spindle fixed to the cylinder, attached to which is a wheel carrying a set of movable weights suspended by a chain, the speed of the engine being regulated by the number of weights. Attached to the wheel and keyed on the end of the short spindle is a pinion revolving with the cylinder, and working in a toothed sector, the arm of which, being fixed on the spindle of the throttle valve, opens or closes it as the oil cylinder moves with the paddle, according to the variation of load thrown on the engine. When used with variable cut-off engine, the arm is attached direct to the cut-off."

From the above brief description of the Allen governor, it will be readily understood that its principles are in accordance with natural laws. It will be seen that the weights are raised and lowered in a nearly vertical line, and, unlike those of other governors, remain the same at every point of their suspension. The high rate of speed used acts advantageously in making the governor very sensitive; and, all parts being lubricated, it works with the smallest amount of friction. The centrifugal or ball principle being entirely abandoned, the movable weights are suspended as easily at one point as another, by the action of the paddle-wheel in the oil cylinder; and from this fact, together with other peculiarities of its construction, gives a direct saving of fuel, and a considerable increase in the power of the engine.

The peculiar action of this governor, which allows the use of a valve of large area, thereby admitting to the engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power, or effecting a direct saving in fuel, and in hundreds of instances doing both. In running an engine with this governor, with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's patent governor valve is constructed with a double disc in a tubular form, and is perfectly balanced, there being no spindle, as in the ordinary throttle-valve, to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, ensuring the greatest possible durability. A large number of highly commendatory reports upon the working of this governor are submitted. It has just been introduced on this coast by the Pacific Iron works, First and Fremont streets, San Francisco.

COAL BEDS.—J. Ferris informs us that extensive coal beds have lately been discovered from the head of the Sevier river through the Panguitch country. The coal discovered is of good class.—*Pioche Record*.

CORRESPONDENCE.

Botanical Excursions.

[By J. G. LEMMON.]

No. 2. The Northern Valleys and Lassen's Peak. (Concluded.) Part IV. Big Meadows and Lassen's Peak.

Escaping in about a week from the friendly people of Indian valley, not, however, without a second call at Dr. Hnut's, young Larsen and I hastened westward along the north shore of the valley, amidst its enchanting groves and dells. At Aheem's ravine we turned off to visit a high valley and the Greenville peaks, a very satisfactory side trip of two days, in which we collected a woolly variety or new species of the beautiful *eycladema*, and a new *Lupinus onustus*. Next day we reached Greenville, a busy mining town, whose locality can be noted from far by the thunder of its quartz batteries and shriek of its engine whistles.

Here a party of four had arranged to join us, but failed to appear. As the weather was fearfully hot, perhaps they profited by the failure.

Alone we climbed the mountain road northward. We felt not the slightest loneliness as we toiled up the flowery way to the pass, 12 miles; besides, we imagined the Rural readers with us, and thought of the rapture that would soon thrill them at the first view, and the interest that would fill their souls for days while exploring in detail the crowding wonders ahead.

Lassen's Peak.

As at Pyramid lake the eye was first riveted to the strange pyramids, so here you first gaze with awe upon the pyramidal mass of snow, rent with comba of black lava, that is reared against the sky in the far distance.

Not alone towers the majestic peak. On all sides it is embellished by scores of glittering pinnacles rising from an alpine region many miles in extent, all apparently covered with snow. It was a refreshing sight that blazing July day.

This grand old landmark is named for Pete Lassen, the old pioneer, and was visited and first described scientifically by Brewer and King in 1863. Next to Mt. Shasta and the lofty group around Yosemite, this is the most noted peak in the Sierra. This result not only from its great elevation—nearly 11,000 feet—but also from its conspicuous position, being in full view of the great valley of the Sacramento on the west, and the great basin of Utah on the east.

This has been availed of by the authorities, who have established Lassen's peak as the corner of three counties—Plumas, Tehama and Shasta.

Big Meadow Valley.

Down before us lies the great, shield-shaped valley, its floor a green and yellow sheet of ripening grass. Like ornamental vines in bas-relief on the shield, are the waving lines of willows that mark the river courses. Round clumps of trees at their sources show the locality of the great springs, of which we have heard so much, while flocks of pelicans, wheeling lazily in the air over the valley, tell where the extensive lagoons are found, green with hundreds of acres of pond lilies.

Land's Big Spring.

Turning to the right, we first visit the great spring near Land's old station. You hear the rush of water an eighth of a mile away. Pressing through the rank grass and over-hanging alders, you walk out on a fallen tree, and a startling yet lovely scene is before you.

A river bursts from out the white quartz rock of the mountain side and cascades down into this deep basin beneath. A line of immense fountains, extending from the cascade through the length of the pear-shaped basin, boil up from the bottom. Circles of waves show the locality and force of these fountains, which even the rush of the mountain torrent cannot obliterate. The outlet of this one congeries of epriaga is 15 to 20 yards wide, and is deep enough to float an ocean steamer. Has the earth anywhere its equal?

This is a type of the springs of this valley, and it is no wonder that visitors from far and near to the valley every summer to gaze upon these stupendous phenomena and to revel in their cool groves. The water is the clearest and coldest you ever drank, resembling the crystal, mountain-distilled Tahoe. It flashes everywhere with silver trout, apparently but a few feet down, but your fishing rod needs 20 or 30 feet of line, so deceptive is the pellucid flood. Paddling out in an Indian canoe you seem floating in air, and frequently put down your hand to determine where the two elements touch.

Peering over the side you see plainly the white toiling eand of the fountain, nearly covered with black globes constantly rolling about. Fishing one up from its home 20 feet below, you find it the globular noston, a ball of rubber filled with jelly. They are all sizes, from bird-shot up to a schoolboy's ball. This is a species of fresh water algae, plants of the lowest order, a simple cell. In the river below are several other species; one a leathery, convoluted mass of gelatinous substance that fills a wash-bowl.

Down where the basin narrows to the outlet,

a pair of white pelicans float, and beives of mallard and divers are in pursuit of young trout. Among the luxuriant flora fostered by this spring, I found on my first trip with Prof. Case the beautiful *Corydalis Caseana*, and several other rare plants.

Reinforcements—The Marlin Brothers.

Crossing fields, meadows and stock-ranges to the farther side of the valley, we are arrested and "corralled," as they say in the mountains, by Mr. Olsen and family, wealthy farmers, similar in disposition to the people of Indian valley.

While drying papers and re-organizing here for the further trip, the neighbors dropped in at night and two brothers, Oscar and Aurelius Martin, arranged to join us, with a full equipment of supplies and the adequate courage, for the exploration of Lassen.

Driving along the dim road up the mountain slopes, with these gallant brothers alongside, our quartette made a very agreeable party, not so small as to lack enthusiasm nor so large as to divide into schisms. These brothers were a study, and by contrast. Oscar, the oldest, was stalwart, round-faced, jovial, daring, appreciative, intensely enjoying natural scenery off-hand. The other, Anrelius, slender, oval-faced, sedate, cautious, quietly appreciative, closely studying with a mind trained by long acquaintance with books and teacher. Oscar carried a heavy rifle to reach for deer or bear, Aurelius a telescope; Oscar brought in rare plants from bog and rock, Anrelius classified them; Oscar admired their appearance and gave the virtues ascribed to them by the Indians, Aurelius demanded their botanical names—carrying a note-book for the purpose.

Around subsequent camp-fires, after the usual scientific discussion, which both enjoyed, Oscar made the welkin ring with song and humorous story, Anrelius recited masterpieces of the old classics, or read original essays.

Hol Lake.

Arrived at Hot Spring valley, all proceeded on foot over a ridge a half mile to see a wonder.

Shrouded in a dense wood is an oval basin 600 feet long by half as wide, filled with nearly milk-white, thickened water, kept boiling hot by fire vents nearly encircling it and apparently the cause also of the incessant bubbling beneath. A narrow, flat rim of white sedimentary matter separates the boiling water from the steaming bluff—the wall of the basin. This border is pitted with msh-pots, blow-holes and miniature volcanoes, from which issue, intermittently, steam, water and mud, roaring, spouting and spluttering, like an immense caldron of garbage. To complete the horrid scene and fix it in your memory, sulphurous gases roar out from holes in the bank and nearly suffocate you. Young Larsen, who had navigated the Mediterranean, exclaimed "How like the *solfataras* of Veenvius!"

Hot Springs.

Two miles farther and the hot springs are heard, a half-mile ahead. This group of noisy rents and vomiting craters is situated in a ravine down which comes a small stream, cold as ice, till it falls into these repelling fire-holes, seemingly a volcanic fissure. For two or more acres on each side the mountain has been fretted away, leaving only the hardest rocks, colored and spangled with iridescent crystals. Great hoppers are frequent, in which rocks are slowly sliding down to be dissolved by the fervent heat below, and carried away in both liquid and gaseous form.

Thoughtfully we stepped from rock to rock around the roaring vents and funnels. The question presses, "Whence this terrible ebullition—this fervent heat? Comes it through a fracture in the crust of a molten globe, or is it evolved chemically by the meeting of antagonistic elements but a few feet below the surface of a solid earth?"

Corydalis Caseana.

Leaving the wagon now and all taking to horse, we wind up through the forest of *Picea amabilis*, or red silver fir, eight miles, and Caseana valley is reached. This is a meadow or swamp of rank herbs and grasses skirted with alders and cut through with streams the banks of which are lined with the new *Corydalis Caseana*, which I have omitted to describe until we came to its home. Here the plant grows to the largest size and presents the finest appearance of any locality yet found. It is often found four to five feet high, and its fragrance is detected 10 rods away. The abundant foliage is pea green, and the robust branches terminate in spikes of white flowers holding a purple swollen palatte in the open mouth, and provided with a large spur or sac of nectar below. The succeeding pods contain four to six black, ariled, hard seeds, that when ripe are thrown to a great distance by the valves of the pods. The slightest breath or touch, and woe to the curious eyes unprotected. With difficulty I have captured a few seeds, as you would catch grasshoppers, and sent them abroad. Thriving plants are now reported in Cambridge, Philadelphia and Washington, also in England and the continent.

King's Valley and Camp.

A prolonged ride over my streams, up steep caving bluffs, along the base of a mountain of rock beautifully chiseled into columns, arches, towers, forts and cathedrals, and through another deep forest tangled with fallen logs, prickly monkeytree and ceanothus, and the near Lassen looms grandly to view through a gap with a green little valley just at our feet. This valley is generally filled with snow until

August, but was now green, owing to the light winter past. It was the rendezvous of Brewer and King and shall be ours.

Choosing a grove of silver spruce, *Abies Pattoniana*, we made beds of fir boughs, lighted a camp fire and sat down to as fine a supper, prepared by Larsen and Oscar, as a king enjoys. How many pleasant evenings that grove witnessed during the week following! Animated discussion, joke, story, song, recitation, crowded the hours until the fatigues of the day overpowered the most hilarious and Morpheus ruled the camp.

Ascending Lassen.

We resolved to see the sun rise from the summit of Lassen and groped three hours through the bushes and up the steep four miles to be enabled to do so, but daylight caught us just at the base of the bald striped cone, which, as we gazed up at it, seemed interminable in its vaulting reach into the cerulean ether. We hoped to look down upon the sun from a perch of 10,000 feet and see him come out from the morning clouds red-faced and battered; but no, the air was clear, and old Sol bounded out of the Humboldt mountains as bright and round as at midday.

Larsen and Oscar proposed to climb directly up the south face. Aurelius and myself passed around to the west of his periphery and took the advantage of a longer grade. A comb of lava jutted out of the west side, extending with but few missing teeth from base to summit. In the gorge to the east of this lies a wedge of perpetual snow, its broad base downward and resting on a plateau of the same. Between this snow wedge and the comb of lava is a space of a few rods of lava dissolved to ashes by the alternate snows and suns of ages. Up this prepared trail we climb. Near the snow the water-soaked ashes admit the climber to the knees, the sharp teeth of lava utterly forbid progress over them.

Happy were we if we found the golden mean. Having a botanical press along, we gathered the flowers by the way, *Eriogonum*, *Penstemon*, *Hulsea*, *Draba*, *Gilia*—families so modified by the Alpine situation as to be hardly recognized. We had left tre and shrub far behind on the plateau below, and fast appearing peaks rose over the forest on every side. Planting our feet carefully in the abutting rocks, we took hold of the comb teeth and pulled our weary frames up from hummock to sag, and from rock to rock. As we were compelled to halt at intervals to breathe and take a swallow of water, the eye roamed over a wide landscape picture that brought brief exclamations, but the light air and great fatigue forbade conversation. We had resolved at the start to keep on the south side of the comb, so as not to catch sight of the peerless Shasta until his head should tower over Lassen's crown, so for hours we kept doggedly toiling up the south face; but about half way up a few rods of teeth are broken away, admitting a full, glorious view of Shasta—not to be described in this place.

The mounting snow now emote our fevered heads, and we gladly took refuge on the north side of the comb, as we pulled up in its shadow. Peaks glistened, and half-broken craters yawned on the west, but we must leave off looking and give all attention of eye, limb and mind to the business of climbing. Slowly we ascended. Often on hands and knees was a dizzy rock ridge passed. Another swallow of water, and a long, terrible struggle amidst sliding blocks of lava, and a high crag is reached, in the shade of which we drop exhausted. But beyond we see the soft, pinnacles alone brow of Lassen envying over, promising better climbing. We shout to cheer each other only one word "Conrage!" and strike heels into the ashes again. Up the soft pinnice in the vertical night, over the sliding shales in the motionless air, and another rock saves the fainting pilgrims! A change of footing—a welcome change! Here the wedge of snow ascending the entire south face of Lassen is found to be connected by a broad band—nansen from below—to a similar wedge-shaped mesa descending on the north side into a vast crater.

It was down this steep of snow on the south side—this precipice of deep pot-holes four to 20 feet across—that Prof. Case and I bounced, three years before, to the base of Lassen, nearly three-fourths of a mile in less than half a minute! Shuddering, I carefully keep away from the brink now.

Across and above this isthmus of blinding snow, 300 feet higher and a fourth of a mile farther, frowns the splintered topmost spur, with a tiny acorn-like monument enmounting it—the goal of our efforts. The interrupted lava comb grew bolder now, straggling and precipitous, but over it only is farther progress. In our haste we miss the best routes, and often have to retrace steps.

Arriving now at the base of the crowning spur, we find it shattered and channeled into labyrinthine chambers that often lead to the sheer precipice on either side. Retracing and trying other passages we emerge at length into daylight, with lichen-covered rocks on edge paying the narrow way before us. A hailing voice is heard, and raising our eyes, there, composedly sitting on the monument, are our daring comrades of the early morning, a full half-hour before us in a direct ascent up the yielding ashes of Lassen's steepest side,—a signal triumph of pluck and muscle seldom recorded!

On the Airy Summit.

It would take a master pen and many long paragraphs to picture the grand scene presented from the monument of Lassen that clear July day. I can only sketch its salient features.

The view embraced 350 or 400 miles north and south, from Mt. Pitt and the snowy Cascade leading the eye a hundred miles over the Oregon line, to the lofty peaks around Tahoe in the middle Sierra. The gridiron bars of the great basin lay revealed on the east, and on the west perhaps 300 miles of the Coast range, from its extreme northern buttes to Mount Hamilton near San Jose. The Sacramento valley lay like a map unrolled, only that it bore in relief the buttes, groves, towns and bridges, and was graven with ravines, rivers and roads.

But the eye is withdrawn from these distant objects in spite of the will, and fixed upon two nearer ones; the one a single peak so lofty, so white, so pure, that all the answering attributes of your soul stir within you at the sight; the other a row of peaks whose composition and contour fill your mind with imaginings most dire, and your spirit shrieks aghast!

The first, the pearly white spire piercing the skies, is the Red man's "snowy throne of Yopitons."

Mount Shasta.

Shasta is the crowning peak of the Sierra, the cynosure of all eyes in the Sacramento valley.

It is 14,442 feet high and in such latitude that the upper 3,000 feet of its spire is almost perpetually covered with snow. It is 70 miles north-west from Lassen, but, seen from the latter, the observed and the observer both being above the humid atmosphere, it seemed not half so far, so distinctly does spur and ravine, crag and cave, appear to the unaided eye. On my first visit to Lassen, three years before, Shasta presented a greatly changed appearance that was truly appalling.

Dust and smoke enveloping the whole country to the height of 8,000 feet, completely obscured the base of Shasta, leaving the great white mass apparently floating on the rolling dun. Where was the iceberg sailing? Might it not come crashing along this way, or worse, topple over and crush our little snowbank to atoms? But to-day it touches bottom, and is fixed to a broad base. To-day its relation to the Sierra is seen, as its grand, culminating head, high-reared and turned westward sufficient to keep watch and ward over the Sacramento valley.

The other object chaining the mind and freezing the blood, is nearer still.

A Phalanx of Volcanoes.

Lassen is the highest remaining spur of a once continuous range of colossal volcanoes crossing the Sierra from east to west. Two of them on the east, nearly in line, may be seen with perfect clarity, round as a caldron, sunk in their tops. Directly opposite is a tall, shining shaft, nearly as high as Lassen, and beyond it similar peaks, all presenting one preëminent side, stratified and colored by volcanic fires. This is perfectly evident from Lassen's standpoint, but several days of subsequent exploration proved them to be a range of a dozen pinnacles, extending 20 miles, each the remaining spur at the side of a vast crater.

Some preëxposed opposing sides so marked as to prove companionship and indicate a crater between them many miles across.

Lassen's Crater.

And here, right at our feet, yawns an immense crater, 800 feet deep and half a mile across. At four points on the rim are left spurs of trachyte lava facing inward, upon the highest of which we are standing, 10,577 feet above ocean level, now; but where were ocean, bay, plain and mountain range in that age when this crater, in company with its phalanx of brothers, with earthquake energies vomited lava and granite boulders from the globe's molten center, and poured them over the surface, perhaps converting an ocean into steam or a primeval forest into ashes, when as yet the vast Sierra in all his present grandeur, was not?

Conclusion.

I have abridged much, yet trepassed far, dear reader, in order to finish the northern trip with this fourth number. I cannot tell you of those other explorations westward; those perilous ascents of pinnacles never before scaled by man, or name the rare plants we brought away. I cannot present the scientific parties we met on our return to Big Meadows, nor even allude to the instruction there imparted by Dr. Harkness with his microscope. We were gone six weeks and traveled 400 miles, bringing in a wagon load of trophies, such as Dr. Gray requested. One of the new ones from the very summit of Lassen he named *Gilia Larseni*, in honor of my companion, John Larsen; and another, growing near the home of the Martin brothers, will be called *Harknessii Martinii*.

And now, dear reader, we have examined briefly some of the valleys and peaks—the decorative jewels, as I called them—of the broad breast of the Sierra. Need I name the last described? The volcanoes of the Lassen phalanx are the blazing stars upon the epanetes; the peerless Shasta is the Koh-i-noor in the crown of Picea Sierra!

RUBBER TREES.—The demand for rubber tires for omnibuses and carriages is again revived, and rubber manufacturers in London and Berlin now offer what is claimed as a strong, durable and elastic tire that will outlast iron on the heaviest traffic. The sanitary advantage of using rubber tires are so great that it is to be hoped this most desirable substitute is really made practical.

MECHANICAL PROGRESS.

Points on Boiler Making.

At the recent session of the British Institute of Mechanical Engineers there was a discussion on boiler making. Some of the points may be of interest to our readers. In the discussion Mr. Cowper remarked that most boilers were fitted much as Mr. Fletcher described when they were made by good makers, and observed that by having a short piece of pipe perforated at the end attached to the gauge cock you are enabled to tell instantly in the dark and by the sound alone whether steam or water was blowing off. He objected to the dome being done away with, but proposed that instead of cutting out the usual sized piece of metal under the dome, perforations only should be made, so that the shell need not be weakened. Mr. Adamson thought that the Manchester Steam Users' Association tests were arranged on an ill considered system. He thought accuracy in punched plates almost unattainable in the hands of skilful workmen, who would always make a seven-eighths inch hole to take a three-fourths inch hot rivet, and that often, especially on Mondays, the men were less sober than desirable, when the accuracy of their work was of course less. He advocated a drilled hole, and that particular attention should be paid to the strength of the rivets. He showed that Sir Wm. Fairbairn's investigations were not original when he first published them. Mr. Fletcher had said that it was not necessary to make the transverse seams stronger than was attainable by single riveting. He thought this erroneous conclusion had been arrived at by relying on the hydraulic test, but they must remember that a boiler does not work with frozen water, but with the steam up, and that in truth the mechanical action is greater longitudinally, so that the transverse seams require to be even stronger. Longitudinal stays were very useful, but the whole structure should be made as uniform as possible. The strength of the rivets as compared with the plates should be 24 to 17, and the plates should be carefully tested, especially across the grain. Credit was given to him for the wrought iron manhole monthpiece, but he never heard of a cast iron manhole monthpiece being used by locomotive engineers. The wrought iron monthpiece is now adopted down to 70 lbs. on the square inch pressure, but below that cast could be used. He believed the time was not far distant when drilled rivet holes would soon be used.

Drilled rivet holes were also advocated by Mr. Welker, of Leeds. He and Mr. Ramsbottom had ascertained six or seven years ago that the joints made with punched holes and hot rivets were not nearly so strong as those made with drilled holes and cold rivets. They also found that the common boiler gave quite as much steam as the Galloway boiler, and they were cheaper. He believed that the reason of the bursting of the cast iron monthpieces shown was that they were badly put on. Mr. Olrick agreed generally with Mr. Fletcher's remarks, but thought the present hydraulic test excessive and damaged the boiler, as it puts in flaws which gradually get larger. The test should never exceed 50 per cent. over working pressure. As to the stays they should be put on in such a way that they only come into use when the other parts begin to fail. He hoped that Mr. Fletcher would not confine himself to horizontal boilers only, but see to vertical also. Mr. Head advocated the use of vertical boilers. He had long had 19 in use, which worked well. Mr. Winch thought that punching need not be untrue if the differential dividing table were used, but some experiments had recently been made by Mr. Kirkaldy which showed that in punched plates the loss in strength was 67 per cent. greater than that represented by the material removed, whilst in drilled plates the loss was just equal to the material removed. Tested longitudinally the figures were: with punched holes 23,299 lbs., and with drilled 27,932 lbs., the difference being about 20 per cent. in favor of drilled holes. Tested crosswise the figures were 22,063 lbs. for punched plates, and 25,600 lbs. for drilled plates, or about 11 per cent. in favor of the latter. Drilled holes induced greater care on the part of the workmen; less iron was removed, and the iron around the holes was not damaged. Mr. Platt thought bad punching had been compared with good drilling, but still there could be no doubt that drilled holes were much preferable.

THE LARGEST IRONCLAD YET. — LONDON, April 29th — The most powerful ironclad vessel ever built was launched at Portsmouth on Thursday, the Princess Louise presiding at the ceremony. The new vessel, the *Inflexible*, is an immensely strong ship, but the 57-ton Krupp gun can pierce her through and through at 2,000 yards distance. When is this thing to stop? Even if it should be found possible to build a ship which would withstand the heaviest gun — and guns of 100 tons, with 19 inches caliber, are now being made for the Italian navy — every vessel is still liable to be sent to the bottom by a wretched little torpedo. The

Inflexible is 320 feet long and 75 feet wide; she has engines of immense force; she will have four guns of 81 tons each. She may be described as a monitor, 75 feet wide and 110 feet long, with walls 41 inches thick, floated by the addition of an unarmored bow and stern. The monitor, or citadel, is 12 feet high, half above and half below the water; within its walls are the engines, the boilers, the base of the turrets, the hydraulic machinery for loading the guns and the magazines. Her guns will carry projectiles weighing 1,650 pounds and measuring 16 inches in diameter. The launch was perfectly successful, and when the immense vessel took the water she was not a bad looking affair as she seemed to be when on the ways. — *Corr. N. Y. World*.

The Sheffield Decline.

English advices report a continued decline of business in the mammoth establishments at Sheffield. How a decline can be subject to treatment under our heading of "Mechanical Progress," is explained when it is remembered that a decline in the great Sheffield center means that progress is being made in the manufactures of the countries which have formerly patronized Sheffield. A correspondent of the *Ironmonger* gives the following interesting items: Markets which the older generation of the business men of Sheffield had to do with in their early days, which they assisted to build up and establish, and out of which they made considerable fortunes are now rapidly withdrawing their patronage from us, and giving it to younger rivals whose goods, if not altogether equal in quality, are much cheaper in price, and that in these days is a great consideration. We are more than confirmed in these observations by the official returns which have been published of his imports and exports for February. The imports of bar iron, iron manufactures, unwrought steel, and some other goods show a steady increase, and to that extent, of course, our own houses are losers. On the other hand, in our exports of hardware to Germany, Holland, France and the Spanish West India islands, India and Australia, we are holding our own, and in some instances the business of this year slightly exceeds that of last year. With what, however, might be termed the great markets of the world — the United States, Spain, South America and Canada — we are doing an ever decreasing trade. The total exports of hardware to these markets during the first two months of this year as compared with last year show a falling off to the extent of £40,000. The falling off in the various branches of the iron trade is even greater. The total value of our shipments of iron and steel in 1874 was £4,373,857; last year it was £3,707,830, this year, £2,935,397. The decline is most marked in reference to the exports to the United States. In the first two months of 1874 our shipments of hardware to that country amounted to £580,344, last year it was £296,820, this year the figures had dropped to £184,869. The only set off against this really alarming decline is an increase of about £20,000 in the value of machinery and old iron sent there. A similar state of things has unfortunately set in with respect to Russia; but some reasons can be assigned for this, and this hope is entertained that the tide will again turn, and that Russia again will be one of our chief customers. The falling off, however, is sufficient to excite the gravest apprehensions. The shipments of hardware to that market in January and February of 1874 were valued at £171,931, last year they were put down at £137,852, this year they only amounted to £52,040. Our manufacturers are hoping good will result to them from the Philadelphia exposition.

SAFE MAKING. — It appears that notwithstanding the many precautions taken by our eminent safe makers to prevent the possibility of any forcible opening of their indispensable manufactures, that the skillful and scientific burglar has lately adopted the method of destroying the works of safe locks by powerful acids, the introduction of which it is asserted renders both the copper and iron of the works soft and pliant in a few moments. To meet this new piece of scientific artifice, Messrs. Chubb & Son have now patented a new lock, which they claim to be so constructed that supposing the whole of the interior works, upon which the key acts, be destroyed, the bolt itself by which the door is held fast shall be left unmoved and perfectly secure. — *London Ironmonger*.

IRON SHEETS THINNER THAN PAPER. — We have heard of iron as thin as paper, but have just had a packet of specimen iron sheets brought to our office, not half as thick as the sheet is printed on. This sheet is .004 inches in thickness; the iron sheets we have received are .0015 inches thick, or only three-eighths of the thickness of the paper. At the same time the iron sheets are so tough as to be torn with difficulty, and so flexible as to bend with almost the facility of ordinary printing paper. These wonderful specimens of iron were made from the rough pig up to the rolled sheets by the Pearson & Knowles coal and iron company, whose skillful manager, Mr. Hooper, has discovered a means of rolling these infinitesimally thin sheets in numbers, without their sticking together. — *Warrington Guardian*.

SCIENTIFIC PROGRESS.

Method of Testing Irons and Steels.

We have, for a long time past, turned to account the action of acids on iron and steel, in order to ascertain their quality; but this action teaches us something further, it enables us to draw conclusions as to the regularity of the process of manufacture which has been adopted, and from this point of view it deserves a wide application.

Iron is, as is well known, attacked by all the common acids, and this action takes place in each of its numerous varieties, as wrought iron, cast iron, and steel; sometimes, however, portions are found which are scarcely, if at all, attacked by the acid, that is to say, passive, a property which is dispelled by bringing them to a red heat, and which has, besides, no connection with their good quality, since the best wrought irons and the closest grained steels are acted upon by acids.

Method of Applying the Test.

After several experiments with nitric, sulphuric and hydro-chloric acids, and their combinations, with mordants composed of the salts of copper, etc., Professor Kick, of Prague, has arrived at the conclusion that a mixture of one part of hydro-chloric acid with one part of water, to which is added a trace of solution of chloride of antimony, constitutes a mordant especially applicable to this purpose. The last ingredient, which was recommended to him by Professor Gintl, renders the surface attacked more capable of resisting oxidation, and has the effect, after well washing with hot water and the application of a coat of protecting varnish composed of Damar resin, of preserving the surface attacked sufficiently pure.

The method of proceeding is always to surround the surfaces, previously prepared by means of a file or hone, with a wall of wax fully three-fourths of an inch high, in the same way that copper plates are prepared for being eaten in with acid in engraving; the acid, heated to a temperature of 52 deg. to 86 deg. Fahr., is poured on to the surfaces, and soon begins to act, as will become manifest by the disengagement of gas. In winter, owing to the low temperature, the operation cannot be performed so favorably. Its duration is usually from one to two hours, and it should be continued, as a general rule, until the texture of the iron be exposed. The progress of the action may be easily ascertained by pouring out the acid every half hour without breaking the wax border, removing by means of a brush or piece of rag the carbon (graphite) deposited on the surface, washing, and again pouring on more acid if the action appears insufficient.

If the chloride of antimony has been added to the acid in proper proportion, but little time will elapse, after the action has commenced, before it will begin to throw down a black precipitate. This is easy to distinguish from the graphite, inasmuch as the latter is not very appreciable, when, for about one and three-quarter pints, is only added a single drop of the concentrated solution of chloride of antimony, which is sufficient.

When the action of the acid has been continued long enough, the wax wall is destroyed, and the surface of the iron is washed by means of a brush with several waters, the first of which is rendered slightly alkaline by the addition of a little lye; it is then carefully dried, and a coat of varnish is applied. If at the end of a few hours there are any signs of oxidation, the varnish must be dissolved with spirits of turpentine, the oxide removed, and the varnish again applied.

Indications Given by the Different Kinds of Iron.

Soft or fibrous iron when of very good quality is attacked by the acid, even when the action is continued for several hours, in a manner so uniform, and with an elimination of the carbon so limited that the surface acted upon retains a dull lustre; a few isolated specks and cinder-like holes being only observable.

Fine grained iron gives exactly the same indications; the surface generally remains uniform, but it is not quite so bright.

Coarse-grained iron and hot-short iron are attacked by the acid with much greater energy than the two kinds above mentioned. Even at the end of about 10 minutes, the surface, especially that of the latter kind, becomes quite black. If the acid be allowed to set for nearly half an hour, a black muddy deposit (*schlamm*) may be removed by washing, and no amount of washing will prevent the surface from remaining black; there will also be a considerable number of small holes distributed over the surface. Some portions of the iron are generally attacked more deeply in this way; others, although they may have become black and a little porous, are better preserved. This appearance will be the more manifest if, after about an hour's action, repeated washings and drying, a fine file be passed over the surface.

Malleable iron or annealed iron becomes rusty, as is well known, more readily than wrought iron; but an interesting fact is that the action of the acid is very violent and irregular.

The color of puddled steel, after being treated with acid and washing, is gray, and of a tolerably uniform shade, the weldings being but little apparent.

The appearance exhibited of blister steel is very like that of puddled steel, and the weldings are also but slightly apparent.

The surfaces of Bessemer steel and cast steel are uniformly gray, the non-homogeneous parts are rare and but little apparent. The softer the steel the more approaching to gray is the color. The action of the acid produces very fine fissures. In a sample of Mueset steel the prepared surfaces were perfectly uniform, but after the treatment with acid narrow transverse fissures were observed over the whole extent. It is probable that the proportion of titanium in this steel was the cause that the surface attacked presented the dark gray color.

Gray cast iron gives the same indications as steel. The attacked surface presents a tolerable uniform dark gray color. In spotted cast iron the white portions remain lighter, and the projecting particles of gray cast iron appear distinctly like black specks or spots.

The cases enumerated above will show the indications given by the principal classes of iron when treated with acid, and therefore the phenomena afforded by pieces composed of different kinds of iron will speak for themselves.

Professor Kick has given many examples of the appearance presented by the combination of different kinds of iron, and adds: "When in the forging of any piece different qualities of iron are united, the acid, when applied to the prepared surfaces, chiefly attacks the quality for which it has the most affinity, and to such an extent that its mordant action on the other portion is much less active than if these portions were exposed alone or singly to the action of the acid." Bessemer steel alone, submitted to this action, presents a gray surface, but, if it is welded to a coarse-grained iron, it is attacked in a less degree.

As to the results of the action of the acid in relation to the method of working iron, the foregoing remarks show that some light has already been thrown on the choice of different qualities of iron in the arrangement of the piles; they also point out that, even with the most simple piling, there is always a considerable crushing of the bands. It is nevertheless possible to draw from the appearance of the surface acted upon by the acid a conclusion as to the position of the bands or bars occupied in the pile. The more uniform is, or may be, the distribution of the pressure in the pile, the less will individual bands become disarranged. The Professor has come to the conclusion that the best method of forming the piles is that in which the welding is so perfect as to furnish the most satisfactory indications when submitted to the acid test.

In conclusion, Professor Kick admits that the samples on which he conducted his experiments were obtained from only one establishment, and that they were too few to admit of general conclusions being drawn from them; he believes, however, that he has conclusively pointed out the importance of this method of testing irons, as well for the manufacturer as for the consumer. — *London Ironmonger*.

WHAT CHEMISTRY HAS DONE. — Dr. J. L. W. Thudichum, in a recent lecture "On the Discoveries and Philosophy of Liebig," delivered before the Society of Arts in London, referred as follows to the position which this latest born of the sciences has already attained: "The youngest of the sciences or the youngest branch of sciences is chemistry, founded by Lavoisier and Dalton; developed by thousands of clear heads and nimble hands, it has in half a century become a recognized power in the affairs of man. It has materially improved his state, and enlarged his mind to conceptions of an elevating nature; it has become a ready test of his reasoning and working power. It has become the handmaid of almost all the elder sister sciences; of astronomy, teaching the composition of distant stars; of geology, teaching the composition and changes of strata and minerals; of physiology, vegetable and animal, teaching about food, nutrition, growth, changes, death and decay; of the healing art, teaching the nature of evils in the shape of disease, and the means of curing or mitigating them. This science, too, was developed by work — work physical and mental; its ways were often rugged, its endeavors misapprehended, opposed, suppressed. And the great men whose names are inscribed upon the roll of its principal promoters will be considered by posterity as benefactors akin to Hercules, removing evils, establishing the good and true."

RELATIONS BETWEEN HEAT, WEIGHT, AND VAPOR TENSION OF LIQUIDS. — M. Pictet has applied the mechanical theory of heat to the study of volatile liquids, making use of the experiments of Regnault, and reduces the following simple relations between their latent heats, atomic weight and vapor tension:

1. The cohesion of all liquids is constant.
2. The differential coefficient of the Napierian logarithm of the tension divided by the temperature is constant for all liquids when referred to the same pressure and temperature.
3. The latent heat of all liquids referred to the same pressure, multiplied by the atomic weight referred to the same temperature, gives a constant product.
4. For all liquids the difference of the internal latent heats at any two temperatures, multiplied by the atomic weight, is a constant number. It thus appears that quantities at first sight wholly independent are really connected by very simple relations, which dispense with long empirical formulas based on observations more or less open to criticism. Furthermore, admitting the law of Dulong and Petit for specific heats, we can further say that the latent heat of all liquids are multiples of their specific heats. — *Bibl. Univ.*

General News Items.

GUSTAV CONLET, the great scene painter, is dead.

Crops in Nebraska are suffering from drouth.

The dowager Duchess of Carnarvon, of Wales, is dead.

The Conservatives in Cork, Ireland, have carried the election, defeating the Home Rulers by a large majority.

A LONDON special to the New York Herald says the United States ship Franklin has arrived in St. Louis.

THE King of Hanover has been made a General of the British army, and the Crown Prince of Hanover's colonel.

The pictures and mosaics sent by the Pope to the exhibition have been entered in the American department by Archbishop Wood.

MARK TWAIN will preside at the opening of the California building, in Philadelphia, which takes place about June 15th.

THE House Committee of Congress has agreed to favor the purchase of \$20,000,000 of silver bullion, not to exceed \$1,000,000 at a time.

THE Senate Committee has agreed upon a bill which will practically restore the franking privilege on letters, documents and packages, under stringent regulations against the improper use of franks.

The President has issued a proclamation recommending the carrying into effect the late resolution of Congress for the delivery of local sketches of the country's progress at various places on the Fourth of July next.

THE delegation of 44 French workmen's corporations have united in refusing to accept the offer of the Government to relieve them of the expenses of sending a delegation to Philadelphia, the reasons for the refusal being that the Government demands the privilege of selecting the candidates.

DEATH FROM THE STING OF A SCORPION.—George Williams died near Tipton, Tulare county, on the 22d instant. While putting on a pair of overalls a large yellow scorpion, which was concealed in the garment, stung him twice in the leg. There were no symptoms of poison for several days, but at that time the leg commenced swelling, with the result as above stated.

Local News Matters.

ELEVENTH INDUSTRIAL FAIR.—The managers of this fair are determined that the Centennial ingredient shall be made manifest in a becoming manner, and it is to be hoped that exhibitors and visitors will do their part in sustaining this character. The fair will be open on Tuesday, August 8th, in the Mechanics' pavilion, which will be open for the reception of goods on Monday, July 25th. We are informed that the managers are now ready to receive applications from exhibitors for space at the office of the Institute, No. 27 Post street, in this city.

GOLD MINING IN SAN FRANCISCO.—Mons. Victor Ressayre, a resident of this city, has achieved sudden notoriety by the reported discovery of a gold quartz ledge on Bernal heights. This notoriety is not simply a local matter. Our exchanges of other States have given the alleged discovery due notice; in fact, the journals in the mining districts are less inclined to slight the matter than those of our own city. This being the case, respect for our brethren of the mining press would prompt us to give the matter a portion of our consideration. In our issue of next week we will give the readers of the Press the result of our observations.

OUR FUTURE MILLIONAIRES.—The New York World indulges in a comparison between the millionaires of California and those of New York, and the habits and advantages in money getting. "Vanderbilt," says the World, "is now the sole survivor of the three New Yorkers whose fortunes ranked with the great fortunes of the world. All this great wealth was the result of hard work, sagacity and economy, steadfastly continued during a long series of years. Nor can any of the great centers of civilization, London, Paris, Berlin and Vienna, furnish the names of three men who have, unaided, achieved such enormous fortunes in the short space of a life. The realization of such exceptional conditions for all manner of commercial and industrial enterprises here in the Eastern States during the remaining years of the century cannot be hoped for again. But over the mountains, on the shores of the Pacific, where untold wealth lies dormant in the bowels of the earth, only requiring the ingenuity and labor of man to bring it forth, there is opened a field for the rapid accumulation of wealth which hides fair to furnish us with California millionaires, some of whom are already among the rich men of the world."

COAL.—Charley Colburn has shown us some specimens of coal taken from newly discovered mines on the ranches of John and George Plank in Mendocino county, and D. W. Sroufe, in Humboldt county. The coal burns readily, and Mr. C. informs us that there is a vast body of it. It will not surprise us if valuable mines are developed ere long. The lack of transportation facilities at present would be a great drawback to the profitable working of the mines, but the time is not far away when this want will be supplied.—*Petaluma Argus*.

SHIPPING COAL.—The first schooner load from the Empire mine was shipped from the Granger wharf last week. The proprietors have contracted to furnish 150 tons daily. Some 80 men are employed at the mine, and 15 six-horse teams are required to transport the necessary amount of coal to the water front. The coal continues to be of excellent quality, and its success is assured. A railroad from the wharf to the mine is a necessity, and various other mines in the vicinity which will doubtless be opened within a few years, will contribute to its support.—*Antioch Ledger*.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

REVINO.—Sonora Democrat, May 27: The mines of Amador county are being reopened in many sections. The work on the working mines is being pushed forward vigorously and prospects in this direction are beginning to flourish. Quartz is looming up and will soon play a very prominent part in our mining interests.

FAIRBANKS.—Sonora Democrat, May 27: Rock is now being extracted from the 300-ft level at the rate of 80 tons per day, which is all the mill is capable of crushing at present. The ore is rather low grade, running about \$3 per ton. The monthly yield of gold reaches \$20,000, about one-half of which goes into the pockets of the fortunate shareholders. About 80 men are engaged in the mine and mill, and over \$10,000 is disbursed monthly for wages and other running expenses. Sinking operations are now being pushed ahead, with the intention of opening up a new level at a depth of 1,000 feet. The shaft is already down to that depth, but it is necessary to go 40 feet further to form what is called in miners' parlance a "snuff" for the drainage of water. It is expected that at the 1000-ft level the ore will run from \$10 to \$15 per ton, rivaling in richness that of the famous Keystone.

TO BE STARTED UP.—The Rising Star mine, near Placer Grove, will be started up almost immediately. The mine is owned by some Oakland capitalists, and is thought to be a paying one, although sufficient rock has never been taken out to test its value. Men have been engaged lately in putting up a house near the mine, and this being completed, mining work is expected to commence forthwith.

IMPORTANT DISCOVERY.—There is a ridge about a mile to the north of the town of Volcano which has been regarded as gold bearing by experienced miners. A tunnel was run some distance in the hill some years ago, but nothing of consequence was found and work was abandoned. Later the Lucas Brothers have taken up the abandoned claim and pushed the tunnel further into the hill. The other day they drifted into very rich gravel, the extent of which is not yet known. Some of the dirt has prospected splendidly. It is thought that an extensive auriferous gravel deposit has been struck, which will probably lead to the thorough prospecting of the ridge from other points.

CALAVERAS.

THE GRAVEL MINES.—Work is progressing steadily in all the claims with results that are in the main favorable. The well known Duray claim, in Chible gulch, is now being worked by tunneling two tunnels having a run of a distance of several hundred feet back into the hill and connected by a drift; a breast has also been started, quite a force of hands being employed in mining the gravel. Work is being steadily pushed in Velt's hydraulic on Tunnel ridge; he has used a good deal of powder during the present "run" with such favorable results that he has become an enthusiastic advocate of bank blasting. The explosion of powder not only loosens up the ground so that the hydraulic becomes very effective, but it also pulverizes the gravel, making it easier to wash. Moser is making sad havoc of the tailings in Spring gulch, having laid the bottom of the ravine bare for upwards of a quarter of a mile in length, and will clean the whole thing out before long. Some of the men engaged in these operations can be formed when we state that the tailings are about 40 feet in depth where he is at present engaged. Emerson, proprietor of the Happy Valley hydraulic, is nearly ready to commence piling; the task of opening the claim has been a heavy one, including the running of a bedrock tunnel 600 feet in length, and grading and building a road about three miles long. Some of the men engaged in these operations are getting old at patient labor and outlay; the tunnel is now completed, and as soon as the flume can be laid through it everything will be in readiness for piling. The tunnel is low enough to drain the mine in its deepest place, and as the claim is one of the most extensive and best fitted up in the county, we look for it to prove both profitable and profitable to the county.

THE NEW MILL AND TUNNEL.—Calaveras Chronicle, May 27: The new mill at long Brady mine—one of Cooper & Cowles' patent crushers—was started last Saturday, quite a number of spectators witnessing the preliminary performance of the machinery. A trifling misplacement of the belt pulleys, however, interfered with the preliminary trial of the mill, but all present were satisfied that it will prove a complete success. Monday morning an immense quantity of gravel was run into the mill, and the mill was kept running steadily ever since. The lack of an "agitator" to assist in getting rid of the pulp, however, has greatly limited the real crushing capacity of the mill, and as that want will soon be supplied, we defer further remark until the machinery is complete. The prospects of the mine are wholly favorable. The entire ledge—at an immense depth—is made up of the gold-bearing gravel, and a considerable portion of the ore is high grade. Rock taken from every part of the ledge "prospects" well, and the vein is so handsomely located that rock can be mined and milled at a merely nominal expense. The plates of the mill make a splendid showing considering the comparatively small quantity of rock that has been run through. When the mill is ready to work from 30 to 35 tons of ore per day, we shall be greatly at fault if the Brady mine does not prove one of the best paying enterprises of that character in the county.

READY FOR PILING.—Piling will be commenced in the Emerson hydraulic, happy valley, next Monday morning. The tunnel in the Happy valley mine has been kept running steadily ever since. The lack of an "agitator" to assist in getting rid of the pulp, however, has greatly limited the real crushing capacity of the mill, and as that want will soon be supplied, we defer further remark until the machinery is complete. The prospects of the mine are wholly favorable. The entire ledge—at an immense depth—is made up of the gold-bearing gravel, and a considerable portion of the ore is high grade. Rock taken from every part of the ledge "prospects" well, and the vein is so handsomely located that rock can be mined and milled at a merely nominal expense. The plates of the mill make a splendid showing considering the comparatively small quantity of rock that has been run through. When the mill is ready to work from 30 to 35 tons of ore per day, we shall be greatly at fault if the Brady mine does not prove one of the best paying enterprises of that character in the county.

WORK RESUMED.—Work has been resumed on the Livermore quartz mine, located near Jesus Maria, upon which operations were suspended last fall. Messrs.

Leyden & Boyle, both experienced miners, have taken a contract for sinking the shaft and commencing work. The mine has received the necessary pump, run by water power, and is now well fitted up for prospecting purposes. The company owning the mine have abundant means at their command, and are exhibiting a laudable degree of enterprise in its development.

RICH ROCK.—Monday last we were shown some very rich specimens of rock from the famous Grasshopper mine at Mosquito. The quartz was fairly studded with free gold in addition to being rich in sulphurets. The rock was taken from the 100-ft south level, which is now being run. Captain Woodworth, superintendent of the mine, informs us that the ledge averages 20 inches in width, and that he has 200 feet of "backs" in readiness to stop from. The work of sinking the main shaft goes steadily. No mine in the county has a more promising future than the Grasshopper.

CONTRACT LET.—A contract has been let for sinking the shaft in the Gwin mine a hundred feet deeper, and the contractors have commenced work. When the sinking is completed the shaft will be 1,200 feet in depth. In the meantime an abundance of rock is being taken from the 100-ft level, and kept in stock for use in the mill. An average of 100 tons of ore being crushed daily. The gross yield of the mine is from \$16,000 to \$20,000 per month, over one-half of the product being net profit.

EL DORADO.

GREENWOOD AND KELSEY MINES.—Democrat, May 20: From Kelsey, under date of May 17th, "R. B." writes as follows: I have lately been looking at the different mines between Greenwood and Kelsey, and will give you the results of my observations. The Taylor mining company, superintended by Mr. Hulford, has purchased the machinery of the Oederberg company, with which the work of sinking the shaft another 100 feet is about to be commenced. The present depth of the shaft is 400 feet, with a large ledge, showing considerable free gold and great quantities of rich sulphurets. The Rockcrans mine, which lies 600 or 650 feet south of the Taylor, is looking splendid. In fact, it is as good a mine as any in our county. This mine, after lying idle several years, was reopened last summer by N. D. Burlingham, under the most adverse circumstances, yet he built a snug five-stamp mill and sunk a shaft about 20 feet, and all the while the mine was being worked. He informed me that last winter was rather heavy for the profitable working of the mine, as he was deficient of machinery to keep the water out of the shaft; yet by perseverance he managed to keep even. The St. Lawrence mine, which has been lying idle for some 18 months, is about to be put in shape for operations under the management of Mr. Ransome, a practical miner of much experience. The sounding of the whistle at the mine to-day reminded our people of old times. We are satisfied that the new company and their superintendent mean business, and know what they are about. They went to get down to the 800-ft level to take out some more of that rich rock, of which there is a sample of about 25 tons in the mill, which shows free gold all through it. At the Mansfield mine, J. L. Smith, superintendent, a new hoisting engine has been put in position, and Mr. Smith will resume sinking at once. Under the influence of these enterprises our people are feeling greatly encouraged, and we expect lively times around this part of the country during this Centennial year.

THE CHAPARRAL MINE.—Democrat, May 27: Under date of May 23d, "R. B." writes from Kelsey as follows: I saw a communication in the Democrat of the 20th from "R. B." in regard to the mines of Greenwood and Kelsey, and the writer has not mentioned the Chaparral, which is now developing with the best of prospects. This mine is situated on the river slope, near Kelsey canon, and is owned by Messrs. Condo, Dickson & Poundstone. These men are practical miners, and doing the work on their mine with a view to permanency. They now have a shaft 40 feet in depth and are still sinking, timbering as they go with white oak. The ledge is now about two feet in width at the bottom of the shaft, and is gradually increasing. We prospected some of the poorest rock we could find, and in no one trial did we fail to obtain good results.

FRESNO.

QUARTZ NEAR DRY CREEK.—Expositor, May 24: We were shown a couple of days ago, by Mr. Armstrong, a large specimen of very rich gold bearing quartz taken from the claim of John McDowell & Co., near the head of Big Dry creek. He informs us that the mine is developing well. A lid ledge of quartz 1½ inches in width has been developed. The rock carries a considerable quantity of silver as well as gold. The mine is the richest of any that we have seen in the county.

INYO.

DEFIANCE MINE.—Coso Mining News, May 27: The new developments since last week have been made in the new shaft from second level north, where has been exposed a fine body of hard soft ore. This shaft has been sunk 25 feet since last report, its total depth now being 90 feet. The drift north from second level is showing fine bodies of ore. This second level drift is to connect with the main shaft north, there being some 200 feet yet to run to make the connection. There are now being extracted from the mine 40 to 45 tons of ore per day, which is a fine record of hoisting works. These works will be put in operation next Monday, when the developments in the mine will proceed more rapidly. Work in all other portions of the mine is going on as usual.

DEFIANCE FURNACE.—Furnace No. 1 has been running constantly and well during the week. There has been shipped for the Goodrich and Co. 75 tons of fuel. Furnace No. 2 has not yet been started, owing to the non-arrival of the water jacket, which has been delayed on the road two or three days longer than expected. It arrived yesterday, however, and will be placed in position and started to smelting next Monday morning.

ROSE SPRINGS.—From Mr. J. K. Maddock, owner in and assayer for the Goodrich and Co., whose mines are located in Rose Springs canon, we learn that on the Garibaldi the vein has been struck at the bottom of the incline shaft, which is down about 100 feet. The face of the drift at the point of the cross-cutting is in splendid ore, which assays \$600 per ton. There is no longer any doubt as to the continuity of the ledge, and its width is now shown by the cross-cut and evidences on the surface to be 70 feet wide.

ON THE NORTH STAR, situated five miles south from the Garibaldi, a shaft has been commenced at the mouth of the tunnel, and from fair average samples across the vein a shaft Mr. Maddock obtained by assay \$301, silver.

KERN.

WORK ON THE ANTIMONY MINE.—Courier, May 25: We have had the pleasure of a call from Mr. Bousbay, of San Emidio, who gives us intelligence of the good progress of the work at the antimony mine. Last week Mr. E. J. Weston, one of the chief owners of the mine, arrived from Los Angeles with 25 pack animals, for the purpose of packing ore from the mine to the furnace. Every preparation has been made for continuous work. Teams have been engaged for moving ore to the railroad. Supplies are going forward under the direction of Mr. Bousbay, who has reached the present working condition through innumerable difficulties. The beneficial effect the enterprise must soon be felt throughout the county.

NEVADA.

MINING NOTES.—Foothill Tidings, May 20: The work of repairing and enlarging the shaft at this mine has

been completed, and work has been resumed in levels below. The mill and machinery have been thoroughly overhauled and everything is in the best of order again. The lower levels are said to be looking better than ever, the ledge being large and of good quality. The new works on the Franklin Allison ranch are nearly completed and will be started up next week.

TULARE.

QUARTZ DISCOVERY.—Delta, May 18: On Thursday last a gentleman by the name of Corrington showed us a sack full of specimens taken from a recent discovery on the Yoko, at a depth of 100 feet. The rock is a little too glassy for a true silver bearing lead, but looks well for gold. Portions of the lead are, however, clouded with black sulphurets of silver; and the cavities of the rock are frequently filled with the yellow chloride of the same metal. The lead is six feet wide, and is one of that class likely to be rendered valuable by recent discoveries lessening the cost of reducing refractory milling ores.

MINERAL KING.—The future of these mines seems bright. Messrs. James Morgan and A. B. Tripp, of San Francisco, have bonded the Loop claim, on White Chief ledge, for the sum of \$300,000, and through their agent have already commenced the development of said mine, by way of contracting for 1,000 cords of wood for mill purposes, and are also erecting a large building that a smelting furnace of the largest capacity will be in successful operation on or before the first of September next.

TUOLUMNE.

TUOLUMNE MINING INTERESTS.—Union Democrat, May 20: The people of this county are almost inclined to grow weary of the good news that their resources in regards to the favorable condition of our quartz and gravel mines. Mines that have lain idle for years, or upon which assessments have been levied to defray the expenses of working, are beginning to look up again under proper management, and there is every probability that before the year closes will be paying large dividends in the way of requiring assessments. The most important information comes from the Sulphur mine of Bonshville, which during the past two months has cleared \$5,000 per month net, and will this month clear between \$8,000 and \$10,000, with rock enough in sight to run the mill three years. This rock is taken from a shaft, for the sinking of which requisitions have been made upon the company, but which it is estimated will now average at least \$100 per ton. Specimens of the rock which would pay between \$150 and \$300 per ton can be seen at the stores of Messrs. J. Hall and E. Richards. The work on the Sulphur mine will be vigorously prosecuted under the superintendence of Mr. Leachman, and it is expected that the rock will improve as the shaft sinks. Another piece of good news is from the Waters claim, near Salsburg, in the development of which thousands of dollars have been spent apparently to no purpose, the only result being the extraction of unreducible sulphurets. Some time since operations were commenced on a new shaft and the result has been the discovery of an eight foot ledge literally seamed with gold. The mill is now running, and the prospects of future large yields from the mine are very better. Sulphurets from the old shaft of this mine have been sent to Grass Valley to be reduced by the Fryer process, but no return has as yet been made. As far as prospects look, the Salsburg and the Gillis lead are in fine condition. We hear a report of immense yields in the Jones & Woodman claim, but the bottom facts are not apparent in this report and we cannot utter a word for their authenticity. The New Albany, near Summerville, is undoubtedly paying, and what is remarkable for the mines in this county, as well as being prima facie evidence of internal prosperity, is the fact that although important improvements have been made upon the property no assessment has been levied. We shall hear more of this mine before long. Prospecting on both sides of the river in the case of Carson and Jacks hills is being vigorously prosecuted, and those engaged in the work are more than content that their efforts will be rewarded largely. Capital is casting its eyes in our direction, and everything now indicates that our mineral resources will in a short time be vigorously and systematically worked.

THE JOE HOOKER QUARTZ MINE.—Independent, May 27: This mine, on Oalder's ranch, 10 miles east of Sonora, owned by Asa Bacon and L. D. Green, shows excellent prospects. The proprietors have run a tunnel 60 feet to the vein at 40 feet deep—run north 80 feet in the pay chute—the vein averaging 18 inches. From this chute they have crushed 11 tons, paying \$34 per ton. The rock they are at present extracting goes over \$100 per ton. The ore from the south chute mills \$18 and \$20 per ton free gold—pay chute 240 feet in length—two foot vein. The specimen brought for our inspection is encouraging, that near the surface, the (sulphurets being oxidized) leaves the gold plastered over the surface as thick as the pits on the skin of a small-pox patient. The rock at a greater depth shows galena, sulphurets and free gold. Some contend this to be a continuation of the Bonshville vein.

THE STAR MINE.—Owned by Jones & Woodman, northeast of Columbia, has recently been incorporated. They have sent three tons of rock to South San Francisco and had it worked by the Philadelphia process, and yielded \$411 per ton, or \$1,233 for the three tons. This rock was taken out at a depth of 120 feet in their main tunnel, heavily impregnated with sulphurets. This mine is one of the richest in the State, and the company propose to work it systematically and on a large scale.

The Carson Gate mine is looking up. The ore in the face of the tunnel at 310 feet is rich in golden sulphurets. By running the ore the gold is exposed in abundance.

Nevada.

WASHOE DISTRICT.

SOUTH CON. VIRGINIA.—Gold Hill News, May 25: This is an old location, or relocation, situated on the north side of the deep ravine at the lower extremity of American flat, near the railroad tunnel. A large amount of work has been done on it heretofore, and a very promising ledge is developed which assays well, and is likely to turn out pretty valuable.

GOULD & CURRY.—Repairing the shaft is slowly advancing, the work of tearing out the old timbers and putting in new being a much slower task than it would be to sink an entire new shaft of the same depth. It is not possible to do so. The preparation of the foundations for the new pumping machinery is going rapidly forward.

YELLOW JACKET.—Cross-cut No. 2 on the 1900-ft level is being steadily advanced, the face in porphyry. A drift north has been started at a point 225 feet east of the winze, to connect with cross-cut No. 2. The winze is 600 feet No. 1, on this level is down 24 feet with quartz in the southwest corner standing quite straight and carrying good ore. Sinking the north winze below the 1900-ft level has been resumed.

AMAZON.—A station is being cut out and a large tank put in to catch up the flow of water on the 300-ft level. The pumps will take the water from the tank and carry it back to the mill. Sinking the main shaft will be resumed as soon as the water tank is completed. The face of the main south drift on the 300-ft level is in vein material.

MINZ.—Sinking the shaft is making excellent progress. It is now down 1,493 feet, the bottom having passed through a very handsome vein of quartz several feet thick, carrying both gold and silver, and looks quite promising. The entire character of the formation is gradually changing, the whole of the material penetrated assuming a much softer and more favorable mineral bearing appearance.

ALTA.—Sinking the shaft had to be suspended during the first part of the week on account of an increase in the flow of water. The water, however, proved to be

only a pocket and is again rapidly receding. The erection of the new powerful pumping engine and other machinery is making splendid progress, the work being pushed with all energy possible at every point. The shaft is now down 425 feet.

UPPER.—The flow of water mentioned in our last report has become so great that it was found necessary to suspend sinking until the new machinery could be set to work. The foundations are already laid, and it is confidently expected that everything will be in readiness to resume work in the shaft in about ten days more.

EAST OVERMAN.—The shaft is actively being sunk, and the surface grading for hoisting works is completed. The bottom of the shaft is in the east range of the Comstock. In the vicinity of the Prospect, Occidental, Europa, and other mines of note, the location of this mine is a valuable one.

PROF.—During the week 15 feet have been added to the depth of the shaft, making a total depth of 272 feet. A small seam of clay and quartz, two feet wide, was passed through, from which came water enough to impede progress somewhat. Two loggers' drills are now working with good effect in the hard rock at the bottom of the shaft.

GLASGOW.—The ore developments in the bottom of the winze in the north drift, now being sunk below the 300-ft level, are of the most satisfactory kind. The ore body shows permeability and the quality continues good. It is the intention to immediately sink the shaft to the 300-ft level, and then to sink another level at a depth of a hundred feet more.

EUROPA.—Sinking the main shaft is making the usual good rate of progress.

CON. VIRGINIA.—Daily yield, 550 tons of ore. The ore elopes and breasts are showing well, and the quality of the ore is as good as at any time in the past. The yield of bullion for May was 100 tons, and the quality of the high standard of the stoppage of the Morgan mill for repairs during the past 26 days, and the adding of the Sacramento mill to the California, making a total loss of the run of two mills for the month. In addition to this, the extraction of ore has been somewhat retarded by repairs which it was positively necessary to make at the 150-ft station, and the rethanking of the shaft for a distance of 100 feet below that station. The erection of the new 80-stamp battery mill is going vigorously forward. The foundation sills and timbers are being placed, the boilers are enclosed ready to raise the smokestacks, and the frame of the entire works is almost ready to raise. Work on the new amalgamating mill is progressing well.

CALIFORNIA.—Daily yield, 300 tons of rich ore, keeping the California and Sacramento mills steadily running. The ore stopes are opening wider and richer than has ever been expected by the most sanguine experts who have ever examined the mine. No mine could be in a better shape for working or the extraction of ore. The north drift from the bottom of the winze below cross-cut No. 6 on the 1600-ft level, connected with the Ophir on Sunday last, greatly hastening the ventilation in every portion of the mine. The north drift on the 1400-ft level will complete a connection with the Ophir at that point in about ten days more, which will give as beautiful and complete ventilation of the entire mine between the 1400 and 1600 ft levels as it is possible to get. The yield of the mine for May will exceed that of the month of April by about \$100,000.

UPPER.—Daily yield, 150 tons of ore. This ore is steadily increasing the reserve at the mills. The ore-breasts on the 1600-ft level are showing splendidly at all points, the ore being of a fine quality and giving evidence of a steady continuation both north and south as well as downward. The north drift on this level is rapidly advancing to connect with the bottom of the north winze which is now being sunk from the level above. The drift has about 30 feet to run and the winze about the same distance to sink to complete the connection. The upraise from the 1300-ft level continues in quartz and low grade ore. The east cross-cut from the north drift on the 1100-ft level, running to connect with the upraise, is making excellent headway.

JULIA.—The south drift on the 1600-ft level has developed a large ledge of lively, healthy, mineral-bearing quartz of a high grade and character. When this ledge of quartz was struck a considerable flow of very hot water was encountered, which has now nearly subsided. The face of the main south drift on the same level is in much softer ground, with a strong seepage of water beginning to come in. On the 1600-ft level the face of the main southwest drift has encountered a flow of water, boiling hot, the temperature showing 180 degrees.

PICOT.—Thus far the main north drift following the hanging wall of the ledge has met with very favorable indications throughout, occasionally cutting through good little streaks and bunches of ore, evidently offshoots from the ledge. A station is now being out near the north end of the drift, at a favorable point, in order to sink a double winze or incline shaft. This is the only way to develop the ledge, but when this the true dip and inclination of it, and accurately determine the most judicious place for sinking the proposed large working shaft.

HALE & NORBROS.—The enlargement of the tank stations in the main shaft has been completed to the head of the incline, ready to receive the new and enlarged pumping machinery now being erected. The erection of this machinery is making rapid progress, the stone work being nearly completed, ready for the foundation sills and other timbers. A strong force of men are employed in the construction of these works, and the whole will be finished ready to start into operation at the very earliest moment consistent with its utility and durability.

BULLION.—The face of the northeast drift, on the 200-ft level of the Imperial shaft, has just cut the hanging of the ledge with every prospect of encountering the ore vein at any moment. The upraise from the 1700-ft level continues in very favorable ledge material, and is making good headway. Sinking both the main incline and north winze is going steadily forward without change of interest. The north drift, on the 1400-ft level, is steadily advancing.

FOURTE JONAS.—The water tank at the 100-ft station is completed, and sinking the shaft has been resumed with the usual energy. The excavations for the new pumping machinery is being advanced at as rapid a rate as possible. The pits for the heavy stone foundations will, when finished, be 21 feet in depth.

WARN.—The shaft has reached a depth of 100 feet, and the sinking is making splendid progress. The boilers are in place and enclosed, the smokestacks were raised yesterday, and the hoisting engine is ready to steam up at any moment. In fact everything is in complete readiness to start, were it not for a delay caused by the non-arrival of the reels at the proper time. These, however, arrived this morning and will be put in place immediately.

BROOKS.—Sinking the shaft is being crowded ahead with all possible energy. The material at the bottom is a mixture of a very promising description, and good progress is being made. A larger and more commodious hoisting work building is about being erected over the shaft and machinery.

SAVOIR.—Cutting out the stations in the shaft for the new and enlarged pump-hubs is going steadily forward. Laying the stone for the reception of the pumping engine is also making good progress. The new machinery being steadily prepared for placing in position ready for work.

PHIL SHERIDAN.—Sinking the main shaft is going ahead at a very rapid rate of progress, the bottom being in soft material and the work being pressed vigorously.

NACAPRA.—Sinking the main incline shaft is making rapid headway. It is now down 300 feet. During the week a vein of finely looking quartz a foot wide was struck in the bottom of the incline, carrying both gold and silver.

BELOCHER.—Daily yield 450 tons of ore. The ore stopes show but little if any change; in fact there is no alteration worthy of note in any portion of the mine. The foundations for the new pumping machinery are getting well advanced, and much of the machinery is already on the ground ready for erection.

DEBET.—Sinking the main shaft going steadily ahead, the bottom in good sinking ground. It is now down 55 feet. A commodious hoisting work building is now being framed and will be erected in a very few days.

NORTH CARSON.—The requisite survey for the long pipe from the main tunnel to the Virginia and Gold Hill water company, to conduct water for the supply of the new hoisting works will soon be completed.

CROLLAY-POTOSI.—Daily yield 110 tons of ore, the average assay value of which is \$31 per ton. Sinking the main incline is going steadily forward without change or hindrance. The east cross-cut from the south drift on the 1350-ft level is steadily advancing without change of interest to reward.

MORNING STAR.—Sinking the shaft is making the usual good progress. Superintendent J. R. Logan is now in San Francisco contracting for steam hoisting machinery. This machinery is to have a power sufficient to sink the shaft at once to a depth of 2,000 or more.

JURICO.—Opening up the drifts on the 800-ft level, preparatory to extending one lying between the 600 and 800 ft levels is going steadily forward. Sinking the main incline and driving the prospecting drift on the 1000-ft level are each making good progress.

DATTON.—Sinking the main shaft is going steadily ahead. It is now down 55 feet below the 700-ft level. Driving the north and south prospecting drift on the 500-ft level is making live progress. Opening out the 700-ft level is also getting well under way.

CROWN POINT.—The east prospecting cross-cut on the 1000-ft level is steadily advancing without a change of interest. On the 1700-ft level the main south drift is being driven forward, but as yet has developed nothing of paying value, otherwise there are no material changes.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is going rapidly forward. Driving the north and south drifts on the 1050-ft level afford no valuable developments to report. The main east drift on the 1250-ft level is steadily advancing.

MEXICAN.—The north drift on the 1465-ft level has been stopped for the present. An opening is being cut on the west side of the ore found on this level, for the purpose of starting a winze downward to prospect the ledge between the 1465 and 1600-ft levels.

SIERRA NEVADA.—Sinking the shaft is going steadily forward, the bottom in fair working ground. Prospecting the 1500, 1250 and 1000-ft levels is being carried forward as usual with no important changes to report.

KOSUTH.—The water has been drained from the 600-ft level, and the drifts at that point are being rapidly repaired and put in good working order again. The flow of water is being kept down by a steady use of the pumps and tanks.

LARRY BRYAN.—The work of excavating for the foundations of the new machinery is steadily advancing. The pits for the stone work will be 23 feet in depth when completed, 14 of which had to be blasted out of the solid bedrock.

UNION CONSOLIDATED.—The face of the north drift on the 1500-ft level is still in very favorable quartz. The drift from the bottom of the winze on the 1455-ft level is steadily advancing in vein material of a very encouraging character.

OVERMAN.—Daily yield, 35 tons of ore from the 1100-ft level. Sinking the shaft below the 1200-ft level has been resumed. The station at the 1200-ft level is opened and a drift started to prospect the ledge.

SILVER HILL.—Sinking the main incline is going steadily forward, the pumps now handling the water with the greatest ease. The prospecting drifts on the 30-ft level north have developed no new or valuable features.

UTAH.—Sinking the shaft is going steadily forward, the bottom still in hard hasting rock. The rate of progress is better than it has been for some time past. The flow of water is gradually lessening.

ROYCE & REARD.—Owing to adverse developments encountered at the bottom of the shaft, and other adverse circumstances, further sinking is discontinued at present, or until the difficulties are settled.

ORIGINAL COMSTOCK.—The double working shaft being sunk to the eastward of the croppings to cut the ledge deep down among the pay ore, is progressing at a very fair rate, notwithstanding the hardness of the rock. The main drift from the ravine at the south end is also being pushed ahead lively to its intersection with the ledge.

LARRY WASHINGTON.—More and better looking quartz and other ledge matter appears at the bottom of the shaft, with a slight increase of water. Sinking goes on at the same lively rate as heretofore. The new pumping and other machinery is working as well as could be desired.

VIVIAN.—The ore-breasts both north and south, on the tunnel level, are showing a decided improvement. The usual quality of good ore is being shipped for milling. The water in the main incline is nearly drained ready to resume work.

IMPERIAL.—The ore body developed by the north drift and winze, on the 2000-ft level, is showing finely, and from sea to much greater extent as the drive opens up. Sinking the south winze is making good headway.

WEST BELOCHER.—The west drift is now in 312 feet, with the face in improved ore from last week's report. The northwest drift is in 200 feet, with its face in good working ground, allowing of rapid progress.

FORDE.—Good work is being done cleaning out and repairing the main drift at the 400-ft level, and the branch drift to the northwest is making excellent headway.

ROCK ISLAND.—The ledge developments northward on the 850-ft level still continue of a very encouraging character. No change on the 650-ft level.

STOCOR.—No changes in any of the prospecting drifts on the 650-ft level. Sinking the main shaft is making good headway.

CALEDONIA.—Sinking the shaft is going ahead at about the usual rate of speed, the ground in the bottom showing but little change.

TRONAN.—The hoisting works are all complete, ready for active operations, whenever the management see fit to so order.

GLOBE CONSOLIDATED.—Driving the north and south drifts on the 300-ft level as usual, the face of both being in lively vein matter.

BEAR & BELCHER.—Everything is at a standstill in this mine, awaiting the completion of the repairs to the Gould & Curry shaft.

NEVADA.—Some little improvement is noticeable in the face of the drift, more quartz and low grade ore coming in.

COSMOPOLITAN.—Face of main tunnel continues in good pay ore, as also does the top of the raise above this level.

DANEY.—The enlargement and repairs of the pump station at the 400-ft level are nearly complete.

LEVITATEAN.—Main drift at the 600-ft level being pushed forward energetically, with good ore indications.

UNIONTON.—Everything in and about the mine progressing as usual. No changes of importance.

MONUMENTAL.—Sinking the shaft is going steadily ahead, the bottom still in very favorable ground.

COLUMBIA.—The enlargement of the shaft is steadily progressing. Otherwise nothing new.

ORIGINAL GOLD HILL.—The rethanking of the shaft is being hastened to the greatest possible extent.

BALTO CONSOLIDATED.—Face of the drift still in favorable working material, and driving ahead.

KNICKERBOCKER.—Sinking the shaft is making the usual good progress.

(Continued on Page 364.)

Practical Objections to the Metric System.

Messrs. Colman Sellers and W. P. Pitman, a committee of the Franklin Institute, to whom was referred a circular from the Boston Society of Civil Engineers, asking the co-operation of the Institute in promoting the adoption of the metric system of weights and measures in the United States, have submitted a report which is full of interest and value. They give a minute account of this confused system that prevailed in France before its revolution, and made a change appear necessary. They also recite the difficulties that prevented the adoption of the metric system by the French people. The report proceeds as follows:

But whatever were the controlling reasons which incited the opposition to a change in France, they have much greater force with us from the absence of motive. We have no such confusion and diversity as the French had, and no such reform is called for. Our money is already decimally divided, and we enjoy already the chief benefits which the new system gave to the French.

If the measurements of the weights and the dimensions of substances, when ascertained, were only to serve as data for complicated calculations, the reasons for adopting weights and measures decimally divided would have controlled the practice long ago. This is actually the case with us in surveying land, which is measured by chains 22 yards long, divided into 100 links; in civil engineering, when submunkments, excavations, etc., are measured by yards and tenths, or feet and tenths, as the case requires; in the measurement of ships for tonnage, when the three dimensions are taken by feet and tenths; and in gauging casks, which is done with a gauging rod marked in inches and tenths.

But the fact is, that this vast majority of weightings and measurements are followed merely by mental calculations; or by a simple multiplication of quantity (whole or fraction) by prices (in decimals), a process which can often be done by vulgar fractions more easily than by decimals.

The meter is really as arbitrary a standard as the foot. About 80 degrees of latitude have been measured, but no two of them have been found of the same length, and there is good reason to believe that the length is not permanent in the same place. The only real thing about it is the rod in the public archives. The length of the meter is to be recovered, if lost, by comparison with the length of the seconds pendulum, and so likewise is the length of the foot or yard.

The meter was adopted in France for the lineal unit, in pendulum, only because the harmonious proportion between the meter and the length of the meridian would bring all local measurements into harmony with the measurement of the world, and would be a great assistance in geography and navigation; but the decimal divisions of the quadrant and of time having been abandoned, and the adopted length of the meter having been found incorrect, there remains not even a sentimental reason for adopting it as our unit of measure. Our own conveniences should be our guide, and overwhelming reasons forbid us to incur the confusion, labor and expense of attempting to make a change of that kind.

In the opinion of your committee the meter, in any shape heretofore adopted, is a less convenient instrument for measurement than a two-foot rule. You cannot fold it into four without breaking the sub-units. If so folded, it would be 10 inches long, which is inconvenient for the pocket. The meter is only decimally divided, whereas the foot rule, beside being divided into tenths and hundredths, is also divided into 12 inches, and gives the seven one-half, one-third, one-fourth, one-fifth, one-sixth, one-tenth, one-twelfth and one-one-hundredth of the foot, and the one-half, one-third, one-fourth, one-fifth, one-sixth, one-eighth, one-tenth, one-twelfth and one-sixteenth of this inch.

By changing our unit of lineal measure for the sake of uniformity with France, we should sever our uniformity with Great Britain, a country with which three-fifths of our foreign commerce is transacted.

The change in our units would entail much greater expense than is usually imagined. The measurements of every plot of ground in the United States have been made in acres, feet and inches, and are publicly recorded with this unit to the land, according to the record system peculiar to this country. Hundreds of years would elapse before we could permit ourselves to forget these old measures. Beside this, the industrial arts during the last fifty years have acquired a far greater extent and precision than were ever known before. Take, for instance, the machine shops, in which costly drawings, patterns, taps, dies, rimers, mandrills, gages and measuring tools of various descriptions for producing exact work and repetitions of the same, with interchangeable parts, are in common use.

It has been calculated that in a well regulated machine shop, thoroughly prepared for doing miscellaneous work, employing 250 workmen, the cost of a new outfit adapted to new measures would not be less than \$150,000, or \$600 per man. If, instead of changing the sizes, we adopt the alternative of giving the French dimensions to the old sizes, the irreconcilable discord between the inch and the divisions of the meter would furnish a precious example of the simplicity of the decimal system.

If new weights and measures are to be adopted, all the scale beams in the country

must be regulated and readjusted; the thousands of tons of brass weights, the myriads of gallon, quart and pint measures, and of bushels, half bushels and peck measures, and every measuring rule and rod of every description throughout the land must be thrown aside, and others, which the common mind cannot estimate, must be substituted.

The great mass of English technical literature would become almost useless, and must be translated from a language which we, and the nations we have most to do with, understand perfectly, into a new tongue, which is strange to most of our people. As a question of cost let those who advocate this change consider it carefully.

To the teacher, to the closet scholar, to the professional man, to those who never handled a rule or a measure, but only use weights and measures in calculation, it may seem merely a matter of legal enactment; but to the worker, the dealer in the market places, to those who produce the wealth and prosperity of this land, this question is a most serious one.

The Franklin Institute has never placed itself on record as opposing true progress; it has always advocated changes which were beneficial and not destructive. In this case a majority of your committee believes that the ultimate benefits of the changes proposed would be of less value than the damages during this transition. They think that the government of the United States has already done all that can fairly be asked of it by the most enthusiastic advocate of the metrical system, by making it legal. Those of us who choose to do so can use that system, and no one can object to it; but for the government to require us to use that, and no other, would be an arbitrary measure which we are neither willing nor able to bear.

The majority of your committee are of opinion, and so report, that the objections to the attempt to adopt the meter as a standard unit of lineal measure are overwhelming, whether we consider the compulsory means proposed, or this and be attained.

All of the objections to the metric decimal system do not apply to the adaptation of the decimal scale to our existing units. In the decimal harmony between the cubic foot and content of water weighing 1,000 ounces avoirdupois, whereby a cube of one-tenth of a foot on the edge becomes the measure of the ounce of water, we have the means of constructing a decimal system of weights and measures which would interfere the least with existing institutions. But your committee do not feel called upon to consider this branch of the subject.

Mining in Nevada County.

A recent number of this *Bulletin* contains a communication from a Grass Valley correspondent, from which we make the following extracts: Twenty-six years ago many of the miners in this vicinity, becoming excited about the quartz ledges so abundant here, gave up placer washing, at which they could then make good wages, and took themselves to quartz mining. Everything in the shape of croppings was eagerly located, the claims at first being taken up in square plats, after the manner of placer grounds, a mode that subsequently led to much trouble. In sinking their prospecting shafts a good deal of ore was taken out, these having been put down in the vein matter. As much of this ore contained free gold, these miners delighted to crush it in hand mortars and exhibit the result, always selecting, of course, the richest pieces for this purpose. So conducted, these crannings would sometimes yield as much as 40 to 50 cents to the pound of ore, beguiling the miner into the belief that a few hundred tons would suffice to insure him an ample fortune. Then these optimists cherished the pleasant theory that their lodes would grow richer with depth, nor did they entertain any fear but they should be able to save every particle of gold they contained. It was in this happy frame of mind, and so reasoning, that the writer found this community of miners on visiting them in the spring of 1851. Scarcely a year passed, however, before their hopes were blasted and their dreams of wealth dissipated. The two or three small quartz mills put up in the neighborhood were able to crush but little of their ore, and what little was crushed failed to yield even a tithe of what was expected. After they had sunk their shafts to a depth of 60 or 80 feet more water came in than they were able to handle, while the most of the ore after passing below the line of permanent water became so highly sulphureted or otherwise so debased that it could no longer be worked by the mill process then in use. Many of the ledges at about this level also pinched out, nor could any further traces of them be found below. In almost every case the wall rock proved to be excessively hard, rendering it very expensive to get out the ore, as the ledges were narrow, affording it in comparatively small quantities. Under these difficulties and discouragements vein mining here early fell into decadence, only a few of the many claims taken up having ever been explored with system or thoroughness. Within an area of 10 miles square about this town more than 2,000 quartz locations have been made, yet of all these not more than a hundred, perhaps, have been much explored, not more than half of this number having been brought to a remunerative or even moderately productive condition. One can almost count on his fingers the mines that have here been developed into largely paying and profitable properties. For 20 years or more one or two mines of this class have been in successful

operation at the same time, and so continued for a series of years, when they would give place to a new set, which came into bonanza as their predecessors passed into a condition of impoverishment, or more often of absolute sterility. The first to distinguish itself in this way was the Allison Ranch mine, which, coming to the front, maintained for several years a good reputation for productiveness. Meantime the Empire, North Star, New York Hill, Rocky Bar and some half a dozen mines of lesser note were earning more than enough to defray current expense, and enough even in some cases to pay handsome dividends. In 1864 the Eureka mine, two miles east of this place, took the lead as a billion producer, which pre-eminence it held for five years, when the ore-chutes that had given it enrichment passed out of this into the Idaho ground, adjoining it on the east. After enjoying for six years the distinction of being the first mine in the district, and one of the most profitable in the State, the fortunes of the Idaho have begun to wane, though it is still paying, and will, perhaps, for some time be able to pay very fair dividends. Just now the rising mines here would seem to be the New York Hill, Providence, Wyoming and Massachusetts Hill, all old locations, pretty well outlived and opened up, and some of which were profitably worked in the early days.

Hydraulic Mining.

While vein mining throughout this section of the State remains thus depressed, hydraulic operations are being greatly extended and prosecuted with unwearied vigor, nothing like the present activity and efficient execution having been seen before in this department of gold washing. Like every other class of mining, this has had its difficulties to contend with. It has, in fact, more than any other, been the outgrowth of hard necessities. Originating among themselves, our miners have had to learn this business wholly from experience, and, while they have not yet brought the system to perfection, every year bringing with it further improvement, they have nevertheless advanced it to a great state of completeness. It is calculated that the crop of gold dust harvested this year will largely exceed any heretofore gathered from our deep placers, intelligent authorities here estimating this increase at 80 per cent. on the product of last season, and 60 per cent. on that of any former year. To the following cause this anticipated gain, should it be realized, will be mainly due. In the first place, the body of snow lying on the Sierra Nevada and on the other mountains whence issue the streams that supply our mines, is unusually heavy. The most of this snow having fallen early in the winter, has since become so impacted by thaws and rain that it will long resist the rays of the sun, keeping the streams that feed the ditches and reservoirs well replenished until the summer is far advanced, and in some localities quite into the autumn. Within the past few years a number of ditches have been excavated for bringing water on the hydraulic grounds, some of these being of large capacity and only recently completed. Several spacious reservoirs have meantime been built in the mountains, while others previously constructed there have been enlarged. Through the aid of these additional ditches, a vastly increased quantity of water can now be delivered where wanted, while these new and enlarged reservoirs will supply the mines with water to a much later period in the summer than ever before, prolonging to that extent the season of active operations. It is now thought that piping will be continued this summer from a month to six weeks later than usual. Last year having been one of extreme drouth afforded this class of miners leisure for cleaning out and repairing their ditches and flumes, refitting their claims and putting them generally in good condition for making a long and uninterrupted run this season, while, as before observed, every year sees introduced into this process some new device, appliance or mode of procedure calculated to economize labor, increase production and add to its efficiency. That the current year, in view of these favorable conditions, will increase the gold yield to the extent estimated, seems probable.

THE DIGESTIBILITY OF MILK.—Dr. Carter, of London, in a paper on the digestibility of milk, after discussing various methods which have been generally used with a view of promoting its digestibility, points out that their efficiency is essentially due to the dilution of the casein of the milk, thus causing the precipitation, on its introduction into the stomach, in a granular form, of what would otherwise be firm, bulky, and compact. He has found, by experiment, that simple dilution with water is insufficient for this purpose, and that this object is far better attained by admixture of alkaline or starchy waters with the milk. He himself gives a decided practical preference to barley water for this purpose.

AMERICAN MACHINERY IN BRAZIL.—A member of the Brazilian Centennial Commission says the American cars are very popular on the roads in that country where they have been introduced. People dislike to travel on the line where are the close compartment carriages of France and England, since they have become acquainted with the light, airy and graceful cars sent out from America. Of agricultural machinery, the same regard to lightness may be made. There is no reason why the United States should not send out ten times as much as she does, except her own negligence of her interests.

USEFUL INFORMATION.

Figures for Fancy.

THERE is iron enough in the blood of 42 men to make a plowshare weighing 24 pounds.

Wild ducks are estimated to fly 90 miles an hour; swallows fly rather faster; and the swift flies above 200 miles an hour.

The cow eats 276 plants, and rejects 218; the goat, 449 and 126; the sheep, 387, and 341; the horse, 262, and 212; the hog, 72, and 171.

In man the temperature of the blood is 98 degrees; in sheep 102; in ducks 107; in ague it falls from 95 to 94; in fever it rises to 102 or 103.

THE beats in an hour of a common seconds clock are 3,600, and 17,280 a common watch; seconds watches beat 18,000 times an hour, or five per second.

WHEN man and woman have attained their complete development, they weigh almost exactly 20 times as much as at their birth, while their stature is about three and one-fourth times greater.

BUT two millions of species of land and water animals and plants are believed to exist. There are at least 100,000 species of plants, and 400,000 of insects only. The species in the seas are believed to be still more numerous. The number of polypi exceeds that of other insects, and the infusoria are not numbered, nor are the parasitic tribes. The species of the whole may even be five millions. If an old species became extinct, and a new one were evolved once a week, the whole would last 100,000 years.

ABOUT the age of 36 the lean man usually becomes fatter, and the fat man leaner. Between the years of 43 and 50, his appetite falls, his complexion fades, and his tongue is apt to be furrowed upon the least exertion of body or mind. At this period his muscles become flabby, his joints weak, his spirits droop, and his sleep is imperfect and unrefreshing. After suffering under these complaints a year, or perhaps two, he starts afresh with renewed vigor, and goes on to 61 or 62, when a similar change takes place, but with aggravated symptoms. When these periods have been successively passed, the gravity of incombent years is more strongly marked, and he begins to boast of his age.

Extraction of Oil from Olive Pulp, Etc.

Sir O. Sebright, British consul at Corfu, includes in a report on the trade of that place some account of the method adopted there whereby oil is extracted from the refuse of the kernels and pulp of the olive.

The method employed for crushing the olive preparatory to extracting the oil is of the most primitive kind. A vertical stone cylinder, of great volume and weight, attached to a shaft, is made to revolve by horse power in a slightly concave bed of the most solid construction. In this receptacle the freshly gathered olives are placed, and by the action of the revolving cylinder reduced to a pulp more or less comminuted according to the degree of pressure. The pulp is then removed and inclosed in flat, circular bags of about two feet in diameter, and then subjected to the action of a strong screw press, set in motion by a lever projecting horizontally, and worked by the united efforts of several men. When under this operation, which is most laborious, the oil ceases to flow, the now strongly compressed pulp is withdrawn and collected in heaps out of doors, where it is left to dry or ferment, according to the accidents of the weather.

Till recent times this refuse was occasionally employed as a manure, and partly used by the bakers for heating their ovens. For this latter purpose it was largely exported to Malta, where it fetched remunerative prices, and this traffic continued until it was put a stop to on the imposition of an export duty by the Hellenic government, which absorbed the whole of the profits previously obtained. The accumulation of this material in the islands, in all of which olive oil forms one of the chief products, had become enormous, in spite of the local consumption for the purposes above stated, when it occurred to some ingenious persons to subject it to a chemical analysis, with the view of turning its properties to some useful account. The result was that it was found to contain from two to four per cent. of pure oil. This discovery once made, in 1869 a firm composed of three enterprising capitalists was established, and works on a large scale were constructed with a view to extracting the oil. The process employed is both simple and ingenious, and has turned out a complete success. It consists in forcing at a high temperature the acid known as "bisulphuret of carbon" through a given quantity of the refuse, which after being reduced to a fine powder by being passed between cast iron rollers, is inclosed in an air tight metal cylinder of great strength, communicating with another receptacle or reservoir, also air tight, through which the acid is forced from beneath, carrying along with it the oil disengaged by its action. After a sufficient time allowed for cooling the reservoir is opened, when the oil, now of a greenish color, but almost odorless, is found floating on the surface of the acid, whence it is baled out and preserved in casks. The acid remains unchanged in its qualities, and but slightly diminished in quantity, ready, with slender additions, for operating afresh.

The quantity of oil thus obtained varies from

300 to 350 tons per annum, calculated to yield a net profit of over 24 per cent. on the capital engaged. The oil has been hitherto exported principally to Marseilles, where it is largely used in the soap manufactories, for which it is found highly adapted. On the score of economy, too, it has its advantages, as it is procurable at a price lower than that of the ordinary oil by about £10 per ton.

METHOD OF LACING A HEAVY BELT.—N. H. E., of Croton, New York, writes as follows to *Leffel's Mechanical News*: Perhaps some of my brother millers have been bothered with lacing up a thick heavy belt, and have it break apart in a week or ten days, and could not find out the reason of its doing so. Let me give my experience through your paper. I have a thick wide leather belt, 18 inches wide and one-half inch in thickness. The first time I used it I put the two extreme ends together, and laced with good strong leather, but it gave out in a few days. I then tried again with no better success, and not being satisfied kept lacing it with different kinds of leather, and spent a whole year in that way. At last I tried this way: Leaving the two extreme ends about one and one-half inches apart I laced with good horse-hide, such as I used in the first place, and I accomplished all I desired. My belt has since been in use over a year and I have not had to repair it in the least. I see tighter and the two pulleys are not over eight feet apart—but with the extreme ends a proper distance apart, so as to be pliable as it breaks around the pulleys, no harm is done to the lacings.

A THERM TELEGRAPH.—A cheap telegraph, useful for certain purposes, can be made in this way: Take two tin cylinders about the size of a small dice box, say three inches long by one and one-fourth inches diameter; cover one end of each with parchment or bladder, forming a drumhead. Pierce the center with a pin and insert a strong thread, and make a knot to prevent its being withdrawn. With the other end of the thread (which may be of any length, say 100 yards or more) do likewise with the other cylinder, and the telegraph is complete. By keeping the thread tightly drawn, in order that the vibration may be perfect, a person speaking or even whispering in one cylinder can be distinctly heard by another holding the other cylinder to the ear. Would not such home-made pocket telegraphs be very useful in fact or in arms, in the army, and in many other situations too innumerable to mention?—*Cor. Scientific American.*

A NEW mode of waterproofing woolen materials consists in boiling four and a half ounces white soap in two and a half gallons of water. Separately dissolve five and three-fourth ounces alum in two and a half gallons water. Heat these solutions to 190 degrees Fah. and pass the fabric through the soap bath, and afterwards through the alum solution. Dry in the open air.

LINING metal for axle boxes: Tin 24 parts, copper 4, antimony 8. Melt together, and add 24 parts more tin.

GOOD HEALTH.

Death of Dr. Hall.

Our Good Health column has been frequently enriched by the writings of Dr. W. W. Hall, the editor of *Hall's Journal of Health*. Dr. Hall died suddenly, falling dead in the street two weeks ago. The *Scientific American* writes of him as follows: Dr. Hall was born in Paris, Ky., in 1810. After completing his education he entered the ministry, and while performing missionary labors found a knowledge of medicine so indispensable that he began systematically to study the healing art. Subsequently he devoted himself to that profession, practicing successfully first in Cincinnati and New Orleans, and latterly in this city.

Dr. Hall possessed an extraordinary faculty for popularizing medical knowledge. He was the first to start a popular journal devoted to the inculcation of the laws of health and correct living, in which the articles were written in so clear and plain a style as to be comprehensible by any one. The fact that the *Journal of Health*, which was issued first in 1853, soon attracted a circulation of 25,000 copies, shows the favor with which the public regarded his labors. Dr. Hall prided himself on writing his whole paper unaided; and as he was master of a concise, epigrammatic way of expressing ideas, it was rare that a copy of the journal could be perused without some useful suggestion being fixed in the mind. Besides his editorial labors, Dr. Hall found time to prepare a number of valuable works on sanitary topics, which have added to his general reputation.

It is a remarkable fact that one so well posted in sanitary laws should have died through the violation of precepts which he perpetually urged upon others. It seems that for some years past Dr. Hall has greatly overtaxed himself in his literary labors, rising at five in the morning, and working almost continuously until ten at night. The physical results of mental overwork are fully known, and perhaps few understood them better than Dr. Hall himself. Yet he fell dead in the street, and subsequent examination has revealed the cause of his death to be degeneration of the heart, one of the commonest results, and according to recent investigations, an almost necessary consequence of an overtaxed brain.

Colors and their Effects upon the Human System.

In relation to Dr. Ponce's statement of the onrions effects of colors and the creative power of the solar rays upon Innacy and other mental diseases, Dr. Newberry, of New York, in a lecture before the Polytechnic American Institute, states that "The colors and rays of light relate to the physical temperaments as stimulants: the yellow color, or ray of light, to the nervous temperament, which is distinguished by a large brain and prominent motor, sensitive and sympathetic nerves; the pink color, or ray of light, relates to the nutritive temperament, characterized by large glandular negative and assimilating parts and an abundance of blood; and the blue color, or ray of light, relates to what I denominate the locomotive temperament, indicated by large bones and muscle, and predominance of the gelatinous tissue. The various temperaments may be stimulated by the colors or rays to which, as I indicated, they respectively relate, and are, therefore, capable of producing either a healthy or morbid influence upon different individuals. A person in whom the nervous system is dominant may have it increased or excited to prostration by the influence of yellow color, or ray of light. A nutritive-locomotive system may be developed so far as to counterbalance the excessive nervousness by the use of purple color, or ray of light. A weak nutritive system may be developed by the influence of pink color, or ray of light, while the same would be injurious to any one of plethoric nature. A weak locomotive temperament may be strengthened by the blue color, or ray of light, while the same would excite a strong person to work or make him irritable. The green color, or ray of light, excites the nervous-locomotive system; the red color, or ray of light, the nervous-nutritive. So that sick or unbalanced persons should have the color of the walls, ceiling, carpets, window-shades, etc., of their particular apartments properly adapted to develop an equilibrium of their physical temperaments, which is the only condition of perfect health and long life required by nature and overlooked by man. All our public assembly rooms should be of neutral colors, with pictures of various subjects to suit the different tastes, so as to produce a neutral effect in the aggregate, in order that each individual might be suited according to his sympathetic and comprehensive attraction."

Poisoned Air in Dwellings.

An exchange says: "A scientific man who takes great interest in the subject of drainage, holds that 'two-thirds of the miasmatic troubles in New York proceed from the kitchen sinks of the city houses. The sink drain gets clogged with grease, and foul odors arise to the upper stories of the houses, and little pale children inhale them all night, until they have scarcely strength enough in the morning to put on their shoes and stockings.' For want of a better remedy, says the *New York Sun*, a common brick placed over the aperture will nearly obviate the trouble, and it should be the duty of every sensible head of a family to see that it is regularly placed there. A woman says that is a man's idea. The duty of every head of a family is to see that the sink is kept clean and free from grease, and that from the drain no foul odors can be thrown back into the house to poison its atmosphere. This is very easily done by a plentiful use of washing soda to kill the grease and keep the pipes free from it, and the occasional use of chloride of lime to sweeten the drain. The cost is but little, and the enemy is cleared out instead of being bottled up, according to the *Sun's* advice. Keep your sink clean and the pipes free from dirt, then clap on your brick if you want to."

To this we add that there is no necessity that the children, or any one else in the house, should inhale such foul air all night; let them sleep with the windows open more or less, in proportion to the strength of the wind, and thus give admission to the outside air, shutting off the inside air of the house from their bedrooms if necessary, and the health of the family will not entirely depend on a kitchen sink.

FLUES AND VENTILATION.—At a meeting of the English Society of Engineers, a paper was read on flues and ventilation, by Mr. A. H. C. Trewman. The author pointed out in the first place, that, in order to keep an apartment in a healthy condition, fresh air must constantly be supplied at the bottom of the room, and the vitiated air as constantly removed. With respect to chimneys, the author observed that their size depended upon the dimensions of the room to which they belonged. A chimney should always be farthest removed from the doors of communication. After considering the theory of ventilation, and tracing the development of the chimney, from a hole in the roof to the more perfect arrangements of the present day, the author suggested two means of preventing air deflected from higher buildings from blowing down a chimney. The first was by placing a slab over the mouth of the chimney, and supported a few inches from it, small openings being made in the chimney at the sides and protected externally. The second plan was to place two converging plates in the chimney near the top, the smoke passing up between them, and any which might be blown back striking on the sloping plates and passing out through side flues. The author concluded by stating that an ordinary house flue should have an area of 18 inches by 14 inches.

MINING SCIENTIFIC PRESS

W. B. EWER.....SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, OEO. H. STROMO
W. B. EWER, JNO. L. BOONE

of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week, 1 month, 3 months, 1 year.
Per line.....25 30 3.00 35.00
One-half inch.....1.00 3.00 7.50 24.00
One inch.....1.50 4.00 12.00 40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, June 3, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Some of the Mines of El Dorado County; The Allen Governor, 353. The Mindeleff Process; Gems and Precious Stones, 360. The Centennial at Philadelphia; Improved Ore Crusher and Amalgamator, 361. Virginia City and the Comstock Mines; Patents and Inventions; How Valuable Mines Should be Recognized and Worked, 364.

ILLUSTRATIONS.—The Allen Governor, 353. The Newspaper Pavilion, 361.

CORRESPONDENCE.—Botanical Excursions, 354.

MECHANICAL PROGRESS.—Points on Boiler Making; The Largest Ironclad Yet; The Sheffield Decline; Safe Making; Iron Sheets Thinner than Paper, 355.

SCIENTIFIC PROGRESS.—Method of Testing Irons and Steels; What Chemistry has Done; Relations Between Heat, Weight, and Vapor Tension of Liquids, 355.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 356.

MINING SUMMARY from various counties in California, Nevada, Montana, Idaho, Colorado and Utah, 357-58-64.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 357 and other pages.

USEFUL INFORMATION.—Figures for Fancy; Extraction of Oil from Olive Pulp, Etc.; Method of Lacing a Heavy Belt; A Thread Telegraph, 359.

GOOD HEALTH.—Death of Dr. Hall; Colors and their Effects upon the Human System; Poisoned Air in Dwellings; Flues and Ventilation, 359.

MISCELLANEOUS ARTICLES.—Rubber Tires, 354. Practical Objects as to the Metric System; Mining in Nevada County, 358-9. The Digestibility of Milk; American Machinery in Brazil, 359.

NEW ADVERTISEMENTS.

Mining Engineer, E. G. Gaertner S. F.; Nickel Plated Screws, E. T. Allan, Agent, S. F.; Desulphurizing Furnaces, Crushers and Pulverizers, Levi R. Greene, Trustee, Boston, Mass.; Stockholders' Annual Meeting, Mark T. Ashby, Sec'y, S. F.; Eureka Foundry, Thompson Bros. S. F.; Phelps Manufacturing Co., S. F.; Stockholders' Annual Meeting, W. O. Wilson, Sec'y, S. F.; Assay Office, Thomas Price, S. F.; Sodium Amalgam, Henry G. Hanks, S. F.; Manhattan Marble Co.—Sale.

MINING ENGINEERING.—Mr. Erich G. Gaertner, who has recently established himself permanently in this city to practice his profession of mining engineering, has opened new offices on the corner of Froot and California streets. Mr. Gaertner has had many years' experience, not only in Germany at the best metallurgical schools, but also in pursuing his vocation in Mexico, Nevada and California. He may be consulted by the mining community on questions relating to mining and metallurgical subjects, the erection of machinery, etc. He is also prepared to report on mines, test ores in the laboratory or on a large scale, or make analyses where necessary. His card will be found in our advertising columns.

NICKEL PLATED SCREWS.—Among the new articles which we present in our advertising columns to-day the nickel plated screw will be found. In articles where beauty and finish in the materials used is desirable, these screws have become largely identified. Car and steamboat builders, organ and piano forte manufacturers, etc., in the New England States—where facility of use and beauty of finish are leading points—have adopted them generally. Those who can appreciate the merits of the higher grades of builders' hardware are requested to peruse the advertisement referred to. By so doing they will be made acquainted with the advantages gained by the use of these screws in the points of durability, economy and uniformity.

THE CHINESE MURDERER.—On Friday of last week the Chinese murderer, Chin Mook Sow, was brought before the Fifteenth District Court for sentence, for the murder of Yee Ah Chin in this city on the 23d day of December last. The sentence was that he be hanged on Friday, the 21st day of July next.

The Mindeleff Process.

Its Theories and Practical Value.

To this age of progress, where all sciences advance at such a rapid rate, where inventions are crowding inventions, where electro-magnetic telegraphs and (alas!) Keelsy motors are springing up, one to last forever and the other to dwindle down to its origin—a tumbler full of water, it is the duty of the journalist to endeavor to discriminate between them, to test and try with the utmost caution, and to leave unnoticed and as unworthy of mention anything where the mysterious forms such an important part of the invention as to force the inventors to shy scientific investigation and to refuse to give scientific reasons for the effects to be produced. In this instance, ignoring entirely all sensational articles which have appeared in our daily cotemporaries relating to our subject, we shall restrict ourselves to an exact statement of the principles governing the reduction of ores by the Mindeleff process, what they can and what they cannot do for the bulk of the ore found on our coast, and whether the invention will benefit us in the reduction of rebellious and low grade copper and silver ores. It may be well to preface our remarks with the statement that the inventor of the process, who is at the same time superintendent of the works, has had no hesitation in giving us in detail the theories on which he bases the success of his process, and has given us every opportunity of closely examining the works in detail.

The Works

belonging to the company are situated close to the depots of the Central and Southern Pacific railroads at the southern end of the city. They are well constructed and evidently fitted up with an eye to permanency, costing, we are informed, upwards of \$12,000. The ore is first brought on to a platform, weighed, and put through a Blake crusher. It is then received into a car and run along the track to an elevator, where it is raised up to the drying chambers, into which the ore is poured. These drying chambers are simply brick ovens open at both ends, and directly below them are the two retorts, each corresponding to a drying chamber above. The ore being deprived of its moisture is then drawn out of the rear end of the chambers and drops by its own gravity into the upper end of the corresponding retort. The retorts are iron cylinders standing at an angle of about 30 degrees, so that the ore will slide down to the discharging point. The retorts are then hermetically sealed, heated, and the gas is introduced from below. At present the works are using gas from the city mains (C₂H₄) which is deprived of two equivalents of carbon by passing it through a cylinder filled with red hot coke and situated between the drying chambers and retorts. A gas burner on one end of the retorts is the means of recognizing (by the burning of the gas) when the operation is finished in the retorts. The escape of the gas is through a couple of cylinders filled with water and situated below. This not only keeps it under pressure in the retorts but also cleans the gas which forces through and admits of its being used over again.

When the charge in the retorts is finished the lower ends of the retorts are opened, and the ore slides down into a car at the front. The car is then run round to the elevator, where it is raised and the car run along again to the reverberatory furnace. After going through that the copper is brought across the building to the refining furnace.

In the case of ores containing both silver and copper, instead of being taken to the reverberatory furnace the ore is raised to the top of the building, passes down through three sets of leaching tubs to the precipitating box. It is then elevated again by a box elevator and carried along to the end of the building to be put through the Freiberg barrels and separators. The machinery receives its power from a 16 horse-power engine. A brick chimney 73 feet high connects with all the furnaces. In the west corner of the building is a neat assay office, with two assay furnaces and everything complete. Near by is the chemical room, in which analyses are made. In the yard is a gas meter, in which a supply of gas is kept. Of course, out of the city the company would make its own gas, but here it is found more convenient to use that provided by the gas company. The works are of substantial construction and quite complete.

We shall now consider the

Chemistry of the Process.

what ores can or cannot be united, what chemical changes they go through, and what advantages are gained or not gained over the old mode. Before doing so, however, it may be well to state that we have already given in this Press a detailed description of the process as far as the working of copper ores is concerned, but that was some time before the works were erected, and, in fact, when the process was first introduced to public notice.

All metallic oxides (with the exception of a few which are not comprised in the general list of noble and useful metals) are reduced by carbon or hydrogen to a metallic state, vapor (HO), carbonic oxide (CO), or carbonic acid

(CO₂) escaping. In ordinary smelting, carbon only is used, and derived from coal, the ores by the action of the heat are to a great extent desulphurized and oxidized and the metal is gained. But by the new process carbon and hydrogen both are brought into action and not only on oxides forming the above mentioned combinations, but also on sulphides (on the part of hydrogen), or chlorides and various others, and light carbonated hydrogen of the formula C₂H₄ is used for the purpose.

Lead ores of over 10 per cent. of lead can not be worked by the Mindeleff process, as the heat necessary for the action of the gas would smelt the ore and clog the retorts. They should as usual be worked in smelting furnaces, and are not affected by the new process.

A small percentage of lead would of course not be a hindrance to the process, but metallizes and adheres in globules to the ore.

Antimony ores come into the same category; a large percentage cannot be worked, a smaller amount evaporates.

Copper Ores.

Oxide of copper will very readily metallize, carbon as well as hydrogen combining with the ore and escaping as vapor, carbonic oxide or carbonic acid respectively, as above stated.

Carbonate of copper will at a moderate heat free its carbonic acid and remain an oxide, which is then treated as such and metallized.

The ores after being metallized are taken to the furnace, smelted and then refined; but the question arises in our mind if there is not just one process too much employed, namely, the metallizing. Carbonate and oxide of copper very readily smelt in coal with a slag, containing a fair amount of silica (if the same is not in the ore) and a so-called black copper results, which one refining makes marketable. Of course a cleaner copper is made by the Mindeleff process, but whether the advantage hereby gained is so great as to warrant the expense of metallizing, we are reasonably brought to doubt.

As to the most frequently found copper ore, copper and iron pyrites, we know that roasting cannot be dispensed with. Roasting means desulphurizing and oxidizing, but if such roasting is done in such a manner as to leave only metallic oxides, we can see no reason why these again should be metallized instead of being smelted as before mentioned.

For poorer copper ores the process may have some advantage, for instead of being smelted after metallization the same ore leached in the above described system of tubs by sesquichloride of iron of the formula Fe₂Cl₃ and metallic copper precipitated by metallic iron.

The chemical action is as follows:

The sesquichloride of iron in the first place changing into chloride of iron and carrying sesquichloride of copper in solution, then the chloride of the latter combining with one equivalent of iron, forming another equivalent of chloride of iron, while metallic copper precipitates. The chloride of iron is then by a blast of hot air and muriatic acid deprived of one-half equivalent of chlorine and sesquichloride of iron (Fe₂Cl₃) remains. During the process of leaching the same is used over and over again, until sufficiently charged for precipitation. This mode may be very effective where the ores do not warrant the smelting process, but there is again one operation which seriously impedes the work, namely: the iron which is generally contained in copper ores and which comes to the leaching tubs in a metallic state, is first dissolved by the sesquichloride of iron, and only after that the copper, for the reason that by the same substance one-half equivalent of iron is more readily absorbed than one-half equivalent of chlorine given up to the copper.

Silver Ores.

Argentiferous galena cannot be worked in this way, but must be smelted as above stated. Chlorides of silver the inventor claims to be able to work on the principle that the hydrogen of the gas combines with the chlorine, forming hydrochloric acid, which escapes, carbon dropping and metallic silver remaining. The following formula illustrates the process:

But why, we ask, the metallization of chlorides (iodides or bromides work similarly) when the same can be readily amalgamated without this process? Amalgamation has to be gone through with, and even considering that the ore by the gas process is greatly decomposed and the grinding of it facilitated, still it has to be ground and amalgamated, and we fail to see the saving.

On sulphides of silver the chemical action is entirely different. Sulphureted hydrogen and bisulphide of carbon is formed, while metallic silver remains. The following formula explains itself (we set for the various forms of sulphides of silver the formula Ag₂S, which is subject to modification).

For low grade ores which are sulphides without iron pyrites this process would be excellent, but unfortunately we have but few of these. Iron pyrites which are bisulphides of iron would have to be roasted before the gas process can be applied, and we are of the opinion that chlorination at once would bring the ores to just as fit a condition for amalgamation as the new process, besides doing away with one handling of the same.

But one kind of ore remains to be consid-

ered; that is where copper and sulphides of silver are contained in small quantities, and without many iron pyrites. Metallization of this ore would be in place, then amalgamation, and finally leaching would gain both copper and silver and be a decided progress in the metallurgy of low grade ores. And that appears to us as the sum total of advantages gained; Pansamint ores and similar ones could come into this class and might be advantageously handled. Low grade copper ores, but only oxides and arsenates, would also be benefited by the new process, notwithstanding the difference hereinbefore mentioned.

As to

Cost of the Gas Process.

We must say that it figures theoretically very low; 40 cubic feet of gas consume two volumes or 80 cubic feet of oxygen of a weight of eight pounds, corresponding to 32 pounds of metallic copper for the oxide and 64 pounds for the protides of copper. For sulphide of silver the same amount of gas would correspond to 108 pounds of metallic silver, and for chloride even more. Neither is the gas very expensive if the light carbureted hydrogen is manufactured, as one ton of coal produces from 8,000 to 12,000 cubic feet of the gas, and one cord of wood from 16,000 to 25,000 cubic feet of the gas; the expense of distillation is claimed to be no more than 50 cents per 1,000 feet, but this many times handling of the ore makes the process somewhat expensive, and the statement that one and one-half to three cents per pound of metallic copper and less for silver would be the approximate cost of reduction needs more corroboration and may be received with considerable caution. Then, again, the cost of erecting works is, for the little that they are able to accomplish, comparatively large, and we doubt whether the same of a capacity of reducing 10 tons in 24 hours can be erected all complete for less than \$25,000.

But notwithstanding all that, we confess that the whole undertaking is based on true scientific principles. We should regret if the venture should prove impracticable, if only on account of the energy and thorough study displayed by the inventor to supply a want long needed. The works are now in full operation, batches of various classes of ores are being worked, and we are of the opinion that any one who desires to examine the operation can do so without difficulty.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANKS.]

(Continued from last week.)

C.—Chrysoberyl, Syn. Cymophane, Alexandrite.

This mineral is found in several varieties. The name chrysoberyl is from two Greek words, signifying golden beryl. When transparent and of a pure yellow color, it is highly prized as a gem. The variety known as alexandrite has an emerald green color as ordinary seen, while by transmitted light it appears columbine red. Another color may also be sometimes seen, a property known in mineralogy as "trichroism." Cymophane exhibits opalescence, sometimes seems to emit a peculiar bluish white light, which seems to emanate from the interior of the crystal. The common variety is of a bottle green color, being colored by oxide of iron. The "choesopites" of the ancients is by some authors supposed to have been the chrysoberyl.

By the following physical and optical properties the chrysoberyl may be recognized:

Crystalline form, orthorhombic; hardness, 8.5; specific gravity, 3.5 to 3.8; composition, (Be₂O₃ + Al₂O₃) alumine 80.2, glaucine 19.8 = 100.0.

Luster vitreous; streak uncolored, transparent, translucent, opaque, sometimes showing an internal opalescence.

Not acted on by acids, B. B. alone unchanged, with soda a slight surface action may be observed, with borax or microcosmic salt a very small fragment may with difficulty be fused. If the powdered mineral is moistened with a solution of nitrate of cobalt and strongly heated it takes a blue color. Possesses double refraction to a high degree. Becomes positively electrical, which it retains for some time.

The chrysoberyl is sometimes known in commerce as the "Oriental chrysolite." Another example of synonymy so perplexing to the mineralogical student.

The mineral is found in loose crystals and rolled pebbles in the beds of rivers in Brazil and Ceylon and Siberia; also in Connecticut, at Haddam in granite traversing gneiss, with columbite, beryl, garnets and tourmaline.

When found in river beds, it is associated with spinel, sapphire, beryl and topaz.

Apatite, fluor spar and adularia are sometimes mistaken for the chrysoberyl, but the latter may be distinguished by its hardness and by the facility with which it may be electrified by rubbing.

The chrysoberyl has been produced artificially by synthesis.

The chrysoberyl is not considered a gem of high character, although it sometimes commands a high price when exhibiting some peculiar beauty, or when taking the fancy of an opulent buyer.

(To be Continued.)

THE President has proclaimed the late resolution of Congress for the delivery of local sketches of the country's progress at various places on the Fourth of July.

[Editorial Correspondence.]

The Centennial at Philadelphia.

Progress of the Exhibition.

The weather for the most of the time since the opening of the exposition has been very unpleasant. It has rained more or less, nearly every day. We are now—Thursday P. M., May 18th—experiencing the third day of a continuous rain, with only slight pauses, at distant intervals. Of course such weather seriously affects the revenues of the exposition; for sight-seeing in a cold rain storm is unpleasant under the most favorable conditions. It is true that one might spend an entire day in admiring the wonderful display of the handwork of all nations as shown in the main building, or in examining and studying the almost endless variety of machinery in the building appropriated to that purpose; but the average visitor prefers to go about a little, for variety, and to get a little fresh air now and then, as a change from the smell of oil and steam, or the confined air overloaded with emanations from the bodices and exhibits of a world in miniature, such as is met with in the building last referred to.

The avenues and most of the minor paths about the grounds are covered with asphalt; but there are many exceptions, and all are just now badly cut up by the progress of "improvements" which are going on in all directions—laying down gas and water pipes, general road repairing, and the use of temporary or permanent railroad crossings, etc. Moreover, the avenues at best are filled with inequalities and depressions, which the water is sure to find and hold with the most provoking persistency. At the more distant points, such as the women's pavilion and agricultural hall, the march of improvement is so extensive and universal, and the mud so deep and stiff, that pedestrianism is almost out of the question, and so is the progress of the rolling chair. In addition to the inconveniences at the grounds, the trouble and disagreeableness encountered in getting there is worse than all else—the main street approaching the grounds is new and unpaved, without sidewalks and almost impassible with Philadelphia clay reduced to mud. This state of things drives almost everybody into the street cars, where muddy boots, wet overclothes and the steaming, stifled atmosphere of the overloaded vehicle is almost unendurable.

These inconveniences might be endured uncomplainingly for a while, were not "Old Prob" so tantalizingly reticent as to any favorable promises for the early future; so I suppose we shall have to keep ourselves with all possible patience, and quietly endure what cannot be avoided.

The Daily Attendance.

It is now said that the attendance upon the first day was greatly exaggerated—that the actual amount of money received showed a paying admission of only about 77,000 people. Since that time the paying visitors have averaged somewhere from 16,000 to 25,000 per diem—according to the state of the weather. The amount of receipts being somewhat less than half these figures, does not make a very encouraging financial exhibit, especially when it is known that the current expenses cannot fall much short of \$10,000 per day. It is said that about 1,000 special policemen are in the regular employ of the Commission. I understand, however, that the Commissioners are not particularly disappointed that the attendance has so far been less than was anticipated, from the facts already alluded to, and from the further fact that the attendance is much in excess of the corresponding days at either Paris or Vienna. It is confidently expected that a considerable increase of visitors will be observed from and after the middle of June; but there will be no large increase of those who come to study until everything is in perfect readiness.

The Noise of the Hammer and the Saw. Still mingles with the music, and is heard, in fact, all through nearly every building and portion of the grounds. Agricultural hall is perhaps the most backward in preparation. Whole sections in both agricultural hall and the main building are still covered with unopened boxes, and artisans are busy over the unfinished work of fitting up. The most of the American exhibitors and the English and their colonial brethren are in shape and busily employed in interesting and entertaining the numerous visitors at their respective exhibits. The Central Pacific railroad agent is still waiting for his lost car of goods. It is somewhere this side of the Rocky mountains, but just where I believe he can't find out. Many of the State buildings are also dragging slowly along, and notably so that of California, which, however, when complete will be one of the finest on the ground. The sections most tardy everywhere are the Spanish, Portuguese, French, Mexicans, Japanese and Chinese. There is no such thing as hurrying either of them. Slowness seems to be characteristic of the Latin and Mongolian races. But judging from what little they show thus far, their full exhibits will be unique, interesting and instructive, by way of showing to better advantage in contrast the progress of other nations.

It is plainly to be seen, however, that the

general exhibit grows more and more attractive with each day's advance. I hope next week to be able to commence my notes on the different buildings, each of which I propose to take up in brief detail. Shall send diagrams of the interior of all the principal ones, which will show the readers of the Press the exact position and relative proportions occupied by the different nationalities. These diagrams, together with the plan of the grounds, already given, and the accompanying description, will be found very convenient guides for persons intending to visit the exhibition—more useful, indeed, than any of the numerous guide books which are peddled on the streets and in the grounds and buildings. The readers of the Press will do well to preserve them carefully.

The State Buildings.

The various State buildings, as indicated in my last, are mostly situated in out-of-the-way places; yet a feeling of State pride and natural curiosity leads all visitors who come from the States which have erected buildings to look them up, and enter their names in the books of registry there kept. These buildings in most instances are costly, and yet of but little practical use or convenience. The buildings themselves, so far as the crowd of sight-seers are concerned, are mostly empty, and you may secure as much privacy in their reception rooms as was obtainable in the average San Francisco street or immediately after the late combination to raise the price of tickets. I believe there are now 25 of these buildings completed or in progress, as follows: Ohio, Indiana, Illinois, Wisconsin, Michigan, New Hampshire, Connecticut, Massachusetts, Delaware, Maryland, Tennessee, Iowa, Missouri, Pennsylvania, Vermont, Arkansas, West Virginia, Mississippi, California, New York, Kansas, New Jersey and Virginia. Nevada, as already stated, has put up her building, and occupies it practically with a five stamp quartz mill. She contributes, however, \$1,000 toward the California building, which will be used as a headquarters for California, Nevada and

the great days of the exhibition. The programme will be made out and published at an early day, so that it may be fully circulated throughout the Union in time to give ample opportunity for all who wish to prepare themselves for participation in such parts thereof as they may select.

Products of Oregon.

As Oregon is the only State or Territory on the Pacific coast which has yet completed her exhibit, I will close this letter with a brief description of the same. The managers of this exhibit are Mr. A. J. Dufur, State commissioner, and Messrs. C. E. Duhois and E. W. Ryan. They have erected and placed in order a magnificent pyramidal trophy, composed of the products of that State. The show is strikingly and tastefully arranged near the center of agricultural hall, with "Products of Oregon" conspicuously emblazoned on either side. The show attracts more attention and inquiry than almost anything else in the entire building. Notwithstanding every package and article is carefully described by a label conspicuously placed thereon, it still requires the almost constant attention of two persons to answer the numerous questions which are asked about the wonderful country which can turn out such productions. The exhibit is a splendid advertisement for Oregon and a practical display of her resources, from which she cannot fail to realize much substantial gain.

The various woods of Oregon are also tastefully displayed in the rough and in various degrees of finish. A section of cedar cut from a tree 198 feet from the ground measured 6.9 feet diameter; another, taken 103 feet high, measured 7.4 feet. It was very naturally inferred from such an exhibit that Oregon had "big trees" as well as California.

There is also a fine display of Oregon dried fruit—by the Alden process—which attracts much attention from its superiority over Eastern fruit dried by the same process.

A Novelty—Cider by the Yard.

I will close my notice of this interesting ex-

THE NEWSPAPER PAVILION.

Oregon. Maine has established her headquarters, and opened a book of registry directly in the midst of her principal exhibit near the east end of the main building, where she is making a very excellent showing of her products and manufactures.

I fear the California building, although it will be quite as artistic and pretentious as any, will nevertheless be a poor place for the headquarters of the emigration bureau. Mr. Martin, I think, will find it to the interest of the cause he represents to establish his headquarters near the California and Oregon exhibit in agricultural hall—some three-quarters of a mile distant from the State building. He will find more inquiries after California there, in two hours, than in the other locality in an entire week. Mr. Scupham, of the railroad exhibit, has fitted up a very cosy little room within the lines of his exhibit, which, with a little enlargement, would make a very convenient, and decidedly the best location for the purpose which Mr. Martin has in view. The State buildings are failures so far as any practical value is derivable therefrom.

The Fourth of July.

It has been determined to make a great day of the coming Fourth. The Centennial authorities have already held several meetings for the purpose of discussing and arranging the details of a programme which shall be commensurate with the importance of the occasion. It is proposed that the demonstrations and celebrations to be provided for shall cover a period of some two weeks, and under the auspices of the Centennial management they will be so arranged that, if possible, no serious inconvenience can accrue to the general public on the Centennial grounds from overcrowding or otherwise. The anticipated rush of visitors upon the great national holiday, and during the period immediately preceding and succeeding it, has necessitated such an apportionment of the more conspicuous features of the great celebration as will supply a special programme for each day for at least two weeks. By this arrangement the rush which would otherwise be confined to the Fourth will be distributed over a number of days, to the manifest comfort and convenience of visitors on all

hibit by calling attention to an interesting novelty shown by Mr. Hampton Kelly. It consists of a roll of a leathery-looking substance, about the color and general appearance of jubbe paste. A small piece cut from the roll tasted very much as a person might suppose sweet cider could taste if evaporated to the consistency of a tough jelly. This, indeed, is just what the substance is. It is made by a process recently patented by Mr. Kelly, substantially as follows: The fresh juice of the apple, before it has undergone fermentation, is thrown, in the form of spray, upon a revolving sheet iron

Braid's Ore Crusher, Grinder and Amalgamator.

cylinder, kept moderately hot by steam, so that the water is gradually evaporated from the juice, leaving the condensed substance upon the cylinder, enveloping the same with a covering about one-eighth of an inch thick, which is then cut and peeled off in a sheet of uniform thickness, which may be rolled up like a sort of oil cloth, capable, to all appearance, of being kept for an indefinite length of time. The sample shown was made last fall. It is said that it will readily dissolve when placed in water, in which condition it forms a very palatable drink. About eight barrels of juice

is thus condensed into the space of one. As a new article of manufacture this substance may come into important use for various culinary purposes, to say nothing of its employment as a drink.

I send you an engraving of the newspaper pavilion, which is a credit to the newspaper interest of the country and to the enterprise of Rowell & Co., of New York, by whom it was erected. Visitors from far off regions will find their home papers neatly filed and ready to welcome them with familiar faces. Each paper can be found by referring to its number in the directory to the building. The Scientific Press may be seen at No. 311. W. B. E. Centennial Grounds, May 19th, 1876.

Improved Ore Crusher and Amalgamator.

We illustrate on this page an invention of interest to miners, made by Charles Braid, of Copperopolis, Calaveras county. It is an improved arrangement for crushing, grinding and amalgamating, and consists in the combination of crushing wheels, with a series of drags within a circular track. From this track the pulverized ore is carried into a flume or sluice box containing a series of peculiarly constructed riffles, where it is amalgamated.

By referring to the engraving the details of operation may be readily understood. A is a circular grinding track with a suitable surface for the purpose, and made of large diameter. A vertical shaft, B, stands in the center of the elevation of this track, and to the lower ends of this are attached the arms, C, for the attachment of animals for driving the machine. To the ends of the arms, D, are attached the crushing wheels, E, which rotate within the track as the arms are drawn around. To the arms, C, are attached the heavy weights or drags, which are thus made to follow the rollers around and pulverize the ore crushed by the rollers.

An opening is made at G in the side of the outer rim of the pan, which encloses the track, and provided with a suitable screen through which the pulp passes as fast as it becomes fine enough. This pulp, together with sufficient water, is carried by a trough or pipe to the sluice box, H, into which it falls and passes over the peculiarly constructed riffles. These riffles consist of inclined planes, I, which the inventor finds to be very suitable when made about four feet long by about one foot wide, and having a rise of about one inch to the foot. From the top of each incline the water and pulp fall down an abrupt face, J, to the foot of the next plane, and so on. The quicksilver is put on the space at the foot of each plane, and is partially retained by means of the inclines, but the falling of the water into these spaces is apt to carry some of the valuable metal up the incline, and it will eventually be lost. To prevent this, the plates, K, are employed, which are placed across the flume and stand at an angle, their upper edges being advanced beyond the lower edges as shown. These plates are so placed that the water and pulp fall from the top of each incline into a space between the face, J, and the plate, and all eddies, currents and splashing take place within this space. From this the pulp is forced down through the mercury, into which the edge of the plate just dips, and then flows gently up the incline, with no tendency to carry off mercury or amalgam, and by this device the inventor saves so closely that he avers that he is enabled to find any traces of mercury or gold in the lallings below the sluice. The sluice may be placed close against the side of the grinder, or, as will be most convenient, it can be set at a short distance away and connected by a pipe or trough so as to leave room for the horse which drives the crusher to pass readily.

This invention has been patented through the MINING AND SCIENTIFIC PRESS Patent Agency. The inventor does not claim separately either the use of wheels or rollers moving in a circular track, or the use of the weight or drag, but he claims certain specified combinations. The machine can be attached to any other crushing machinery and reduce the ore rapidly to an exceedingly fine condition. It has been well tested, and can save the finest flour gold. The machine has been used for six months steadily at one mill, and one-third of the gold taken out was saved from the waste by this amalgamator. The inventor is an old miner and mechanic, and has paid great attention to the subject of saving gold. The machine is cheap, simple in construction and not liable to get out of order. It can be used with profit in cement and placer mines. It is easily packed from place to place, and readily adjusted. The inventor is ready to take it around to work tailings to prove its usefulness. Quite a business could be made with one of these machines in gleaming from old diggings. State, county or individual rights to use this machine can be bought on reasonable terms. The inventor may be addressed as above for circulars and further information.

Mayor Bryant, Mark L. McDonald and R. C. Page of this city, with Robert Denton of Los Angeles compose the "Star oil works company," which, with \$1,000,000 capital, is building an oil refinery at Ventura.

THE VIRGINIA GOLD GRAVEL MINING COMPANY, whose mines are located near the Dardanelles company, Placer county, have recently planted new machinery on the ground and recommenced work after a lapse of many years.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best E-stablished Reputation,

In which, at great expense, the different Steam
Pumps were tried under every test known
to experts, the Examining Committee
of the Tenth Industrial Fair of the
Mechanics' Institute have
awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.**

We are prepared to furnish PUMPS UNDER
CONTRACT, guaranteeing their ability to
perform any specific work for which
steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER
FROM WELLS; STEAMER AND
SHIP PUMPS, ETC.

We would also call the attention of those
interested, to our Direct Acting Deep-Well
Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps
FOR HANDLING QUICKSILVER or heavy
liquids.

Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

(Continued from Page 358.)

ELY DISTRICT.

ALPS MILL.—Pioche Record, May 23: The Alps mill for the last 15 days has been crushing 20 tons of ore daily and running steadily six pans.

BULLION SHIPMENT.—Wells, Fargo & Co. shipped bullion yesterday valued at \$3,822.

RAYMOND & ELY MILL.—The Raymond & Ely 30-stamp mill at Bullionville started on Saturday to run to its full capacity, that is the 30 stamps. For some time it has only been running 15 stamps.

TOCQUEVILLE ORE.—Dufferin, Forsythe, Dodge and Pinkham arrived yesterday in Pioche with a large amount of ore from the Toquerville mines, which will be worked at the Alps mill.

RIOB ORE.—Joe Gargus, an old prospector and miner in these diggings, a few days ago brought to town some very rich specimens of ore from White Pine mountain. It was free milling ore, and would average not less than \$5,000 per ton, and he claims to have lots of it in the mine. The name of the mine has escaped our memory, but it is located on the west side of the mountain and not far from the celebrated Trench mine.

Arizona.

MIOA.—Miner, May 20: While at the Peck and Prince mines last week we saw sheets of mica, popularly known as isinglass, several inches square and in layers two inches thick, taken from a ledge of that material, by Mr. White, not far to the eastward of the Prince and Black Warrior.

NEW CLAIMS.—Gila, May 13: The following mining claims have been recorded during the week in Recorder S. W. Carpenter's office: May 6th, Bombach's Black Lead mine, two and one-half miles south of Camp Bowie, located by Otto Bombach. May 11th, two placer claims in the Smith mining district, located by T. Armstrong. Placer claim, Granite mountains, located by E. D. Hudson, C. Bent, W. Buck and F. C. Jones.

Colorado.

SAN JUAN MINES.—Colorado Springs Gazette, May 20: The rush to the San Juan mines is still on the increase. More are passing through this week for that country than during any previous week. So far as we have been able to learn, they are about equally divided between the Lake, Animas and Uncompaghe districts, with a few to the La Plata and San Miguel. The most encouraging prospect of the present time, and for the future, is the large amount of capital which is now coming in for investment in mines and works. The apparent rush to distribute over almost the whole mining range of the Territory, but the bulk of it, at present, attracted to the several districts of San Juan.

PARK COUNTY.—Lone Star mine, Mosquito district. The shaft of this is now down 150 feet and levels are now being run at this depth. It is the intention to continue the level on the lower side to the surface, and then work the mine through this drift. This will not only deepen the mine but also give it ventilation to the mine. The ore of this mine has steadily increased as depth has been gained. At the present depth native silver in considerable quantity is found.

SUMMIT COUNTY.—Messrs. Willey & Clary have effected arrangements for developing the Tiger, Tiger Extension and St. Cloud lodes, situated on Glacier mountain, Snake River district. These are among the most prominent lodes in Summit county, and lying as they do, between Montezuma and St. John, are most advantageously situated as regards market for ores.

Idaho.

LOCAL MINING NEWS.—Statesman, May 27: The finest looking gold brick that has been seen in this vicinity for a long time was made up by Simondt on Tuesday from Belle Peck crushing. Its total value was \$10,202.73, the proportion of which in gold was \$9,574.23 and the value to the ounce \$11.56. There were 72 tons of rock used in making this bar, resulting in an average of nearly \$142 to the ton.

COAL CRUISE.—Everything is flourishing in connection with this mine. The workmen have just received another month's pay and are happy.

FRANKTON MINES.—There has been unusual hustle and activity in these mines for the past fortnight. There is not an idle man in the new camp.

SOUTH MOUNTAIN MINES.—The mines that are being worked in this camp are looking well, and the great impression is that the new company controlling most of the mines here will have a force of men at work in a few weeks, but this furnace will not probably be started before the month of August.

THE POTOTI.—Mr. Peck informs us that the Pototi is looking first-rate, and he has every reason to believe that developments will show that he has got just as good a thing here as he has in the Belle Peck.

Montana.

A GOLD LUMP.—Independent, May 28th: Our reporter saw yesterday at the banking house of Hirschfeld & Co. an egg shaped lump of refined gold valued at \$4,000. It came from Last Chance gulch, and is of superior quality and fineness.

Utah.

MINING NOTES.—Salt Lake Tribune, May 26:—Six of our mining districts will turn out more than the usual amount of refined bullion this season. These districts are Uintah, West Mountain, Tivito, Ophir Camp Floyd and Leads. The placer diggings of Bingham are well supplied with water, and are said to be panning out well. The Camp Floyd mill is running regularly on ore of this district, and is doing a nice business. The Bay City run of which is delving beneath the Emma, has a vein of ore 20 feet wide between well defined walls. The ore assays away up in the hundreds, Utah, during the month of March, which is regarded as the worst in the year, produced \$745,000 worth of base bullion, \$75,000 refined bullion, and \$4,000 copper—making a total of \$824,000.

A Weekly List of U. S. Patents is sued to Pacific Coast Inventors.

Virginia City and the Comstock Mines.

NUMBER FIVE.

[By our Resident Correspondent.]

The next in order to claim attention as we follow the lead south is one of the best known as it is also the oldest well defined location on the Comstock. The Ophir was a portion of the ground which in 1859 came into the possession of Comstock and his partners, and it was through this claim that his name was given to the lode. About 1853, the Grosch brothers claimed to have discovered silver ledges and located a claim where Virginia City now stands, calling it the Pioneer, and the present Ophir ground is a portion of this. There has always been some doubt whether the Grosch brothers or Finney (known as old Virginia) made the first location. The original notice of location made by Finney was found and published, but that of the Grosch brothers, though said to be in the possession of private parties, has never been produced, hence it was impossible to compare dates. But neither was sufficiently permanent or distinct to be perpetuated, and the Ophir, being able to trace its origin and progress in an unbroken line from the time it was worked by John Jessup in 1859, for gold, has an undisputed right to be called the oldest. After it was fully established that there was an immense wealth of silver as well as gold in the ledges, in 1860, the Ophir company was incorporated, and work begun in a shaft due west of the present works, and well up the side of the hill. In those days the vein was thought to pitch west and would be found far under Mt. Davidson, and western locations were as much sought after as are the eastern to-day. This shaft was worked from the date of the incorporation of the company to 1867, during which time a depth of 700 feet was reached, striking that ledge which is called in Commissioner Raymond's reports the third ore body. This yielded immense quantities of rich ore, and in some places was of great width, but gradually narrowed down, and at 700 feet pinched out entirely. During this working the company was enabled to pay dividends aggregating over one and a third millions.

In 1867 the old shaft was abandoned and preparations made to work in the new one on a much larger scale, and from that time until the destructive fire of last October, prospecting and exploring was vigorously prosecuted. When the new shaft was begun there was a better appreciation of the extent to which mining would be carried in this district, and consequently arrangements were made for operations of much greater magnitude. Hoisting works and pumping machinery of greater capacity were provided, and the shaft was made with four compartments—three to be used in hoisting and one as a pump shaft. The fire destroyed, of course, everything that could be burned on the surface, and damaged a great deal of the machinery—some of it irreparably; but with the energy which characterize all the operations at this place, the work of renewal and renovation was immediately begun and rapidly pushed to completion, until at this date you would have to search elsewhere than at the Ophir for any traces of the great fire.

Instead of tracing the progress of the work through each year, which would not interest many, the effort will be made to give an accurate account of what has been accomplished by describing the present condition of the mine, though despairing of giving to any one, not familiar with this work, the clear idea of it which was imparted to me by means of an impromptu chart and an exploration of the mine. The whole depth of the perpendicular shaft is at this date 1,640 feet; though there is a 1700-foot level reached by a shaft from the 1465-foot level, 360 feet east from the main shaft. There were several levels above and at 500 feet, with a good deal of drifting, but being of little consequence and showing no developments they were not cleaned out after the fire. The 700-foot level was also of no consequence, beyond the fact that here the largest body of water was found, and the largest tank is situated. The next level is at 1,100 feet. A great deal of work was done here in 1872, there being encouraging indications that the rich ledge would be found. The vein was exposed for 83 feet north and south, and 200 feet east and west; the eastern portion being nearly all quartz. Work on this level at present consists of cross cutting east. At 1,300 feet there are no special developments. From this level there is an upraise to the 1100-foot level and from the upraise, 50 feet above the 1300-foot level, there is a connection with the California mine all the way in ore. At 1,360 feet another connection is made with the California, and a third on the 1465-foot level, both in ore. On the 1465-foot level a great amount of work has been done. It is from here that connection is made with the Mexican north, for the prospecting of that mine, as well as with the 1600-foot level of the California south. What appeared to be two ore bodies are found here bordering on and extending into the California; but both above and below, these bodies are found to come together into one, being divided by a "horre" for about the depth of 85 feet. The ore from these bodies is being worked at present. Still on the 1465-foot level, and 361 feet east of the main shaft, there is a perpen-

dicular two compartment shaft, communicating with the 1,600 and 1700 foot levels. This shaft is fitted with an engine run by compressed air, and is at present working on the extension of the 1700-foot level towards the main shaft. The principal development of the 1500-foot level is a long drift running towards the California lins, and discovering the points at which the divided ore body above referred to is reunited. The next level is at 1,600 feet, and this is virtually the termination at present of the main shaft, though it is intended to continue it to the 1700-foot level, which is now reached only through the east shaft from the 1465-foot level. It is from the 1600-foot level that most of the ore yield is being taken. The ore body here is 100 feet wide and is found 80 feet farther north than at the 1500-foot level. The ore breasts here are in fine working order, the ore of fine quality and promising to continue north and south and in depth. A north drift on this level will soon connect with a winze which is coming down from the 1500-foot level. In the 1700-foot level, its extension towards the main shaft and preparations for thoroughly prospecting it are actively going on.

Much other work has been and is being done in various portions of the mine, such as cross-cutting and running drifts and sinking winzees for ventilation and for convenient communication; which, though very necessary in the system of development adopted, are not essential to a correct understanding of the general plan. The future working of the mine has been determined to be by an incline shaft which starts from the 1600 foot level and which the machinery and appliances, prepared for this purpose are capable of sinking and operating to a depth equivalent to 3,500 vertical feet. Its direction will be east in the west wall and keeping close to the lode. The incline will be worked by a set of machinery independent of that used in the main shaft, and at the 1600-foot level there will be an ore house, into which the "giraffe" used in the incline will empty itself. From thence the ore or waste will be taken, in the usual way, up the main shaft.

It is evident that the results attained and the work projected could not be accomplished without machinery of great power and capacity, and of the best construction. The first to speak of are the two hoisting engines; one having a 20 inch cylinder and 36 inch stroke, the other an 18 inch cylinder and 27 inch stroke; each provided with two reels, but operating only one rope apiece at present, as but two compartments of the shaft are being used. It is intended to put another rope on the larger engine with a reverse motion, so that one cage will descend while the other is being drawn up. A 20 horse-power engine runs all the machinery of the machine shop, drills, lathe, planers and circular saws. Still another, a 10 horse-power, operates a Baker's rotary pressure blower. A Burleigh No. 7 air compressor, capable of furnishing over a million cubic inches of air a minute, provides power for all the underground machinery, consisting of two hoisting engines on the 1,465 foot level, four or five blowers, and all the Burleigh drills that are or may be used. The compressed air is received in two large reservoirs just outside of the hoisting works building, and from there conveyed in six inch pipes to another reservoir at the 1,465 foot station, and thence distributed to where it is needed. Several reserve pieces of machinery are in readiness to be used in case of accident or any emergency. Among the rest one of Booth's compressors. All this machinery is in the main apartment of the shaft house. In an adjoining room is the 285 horse-power pumping engine, which is capable of running 14 inch pumps at a depth of 3,500 feet. There is one compartment of the shaft allotted solely to the pumping arrangements; and thus the tanks are reached at any station without interference with hoisting work.

Eight hoilers are required to furnish steam for the engines enumerated, and two more for the engines which will work on the incline. The incline machinery is also in the main building, but being independent of all the rest was reserved for separate notice. Two engines, of a combined capacity of 320 horse-power, in connection with a hydraulic of 173 pounds water to the square inch, furnish an aggregate of nearly 700 horse-power, with a capacity for work at a vertical depth of 3,500 feet. The advantage gained by this combination are principally economical; two-fifths in fuel alone being claimed. In hoisting, the pressure of the water is calculated to balance the weight of the rope and the car, leaving only the weight of its contents for the engines. In the act of lowering, the course of the water by a simple device is altered, and the weight of rope and car operate to force the water back up to the reservoir, so that none is lost but is used over and over. One engine man manages all the levers connected with the steam engines and the hydraulic. A round wire rope will be used, wound around a conical shaped drum or reel; the cone shape being necessary to regulate the speed in raising.

The application of this hydraulic engine—which is a patent of Sir Wm. Armstrong—to this auxiliary use originated with Jos. Moore, Superintendent of the Risdon Iron and Locomotive works, and J. F. Thompson, master machinist, who superintended the erection of all the works at the Ophir.

Another hydraulic engine is in operation at the ore house, which is used to elevate, to a convenient height for loading into cars, all the ore sent to the mill by rail.

The object of these letters being solely to give information of such general character as

will interest all your readers, opinions and speculations are, for the most part, not expected or desired; but it may not be amiss to record the general impression received as to the future prospects of the mine. Indeed, the value of the ore body, as far as exposed, is simply a matter of calculation, and while its extent is not determined, it has been found with increasing depth to increase steadily in bulk and in richness. The present yield—of about 180 tons—is not increased, yet only for want of milling capacity. This quantity keeps the mill fully supplied and accumulates a reserve. What is now in sight, and what is being developed in the present system of prospecting, furnish well founded expectations that the future prosperity of the Ophir may exceed that of her brightest days in the past.

It was my intention to have spoken of both the Mexican and Union Consolidated, which are worked through the Ophir shaft; but finding this letter already exceeding its prescribed limits, must wait until next week.

Virginia City, May 31st, 1876.

How Valuable Mines should be Recognized, Prospected and Worked.

[Written for the Press.]

NUMBER ONE.

Under this title we shall give a number of articles which will be entirely for the benefit of the practical miner; we will explain first the theories of the origin of mineral ledges, and their formation, then their contents as far as copper, lead, silver and gold ores are concerned, and finally give the mode of working the different classes of ores in the most simple manner, so as to enable men of small means, possessed of mining property, to work and these themselves the products of their mines.

Taking it for granted that all mineral deposits, ledges, lodes or veins are originated by volcanic eruption, the liquid mineral matter breaking its way to the surface of the earth, a conclusion as to the origin of the different formations of veins is easily derived.

True Fissure Veins.

When the above mentioned liquid mineral matter forced its way to the surface it aoted strongly against its overlying strata, thus forming a hanging wall, in many cases as smooth as if polished. It is not necessarily inferred that the pitch of such ledge should be steadily in one direction, but according to the firmness of the strata met with it might be altered and angular; there is, however, a general tendency of all metal bearing ledges to run in a northerly and easterly direction and to dip towards the east, caused no doubt by the fact that the earth revolves around its poles and from west to east.

Blind ledges merely lack the force of breaking the outer crust of the earth and are found at varying depths, but with the same description of hanging wall as fissure veins; they are, in fact, such in every detail but without croppings on the surface.

But wherever such liquid mineral matter is possessed of more than ordinary force, a certain amount of it may run over and rush into any crevice existing below, thus causing

A Wedge Shaped Mineral Deposit.

wide at the top and giving out wherever the crevice terminates. In this case the foot wall is the one acted upon and will be found smooth, while the hanging wall allows the liquid to settle and cool without offering resistance, and retains in consequence its natural broken appearance.

There is yet one formation frequently met with, caused by other than volcanic action; that is the so-called

Mineral Slide.

In a later period water or glaciers may have broken off large pieces of metal bearing ledges, carried them away long distances, together with all their surrounding strata, and deposited them elsewhere. They may offer all the appearance of fissure veins but soon terminate abruptly and upon strata of entirely different formation than the ones which they are possessed of. We shall give in our next the mode of recognizing and prospecting the above mentioned classes.

It is unquestionably a contagious disease that is known to be prevalent among a populous class of the community. GLENN'S SULPHUR SOAP will cure it. The Board of Health should order a supply of the Soap for that purpose, at public expense. Sold everywhere.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867. The most complete treatise. Published at this office. Price \$5, post-paid.

THE EXPLORES', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price, cloth, \$10.50; in leather, \$12; postage 50 cts. Sold at this office.

SEVERAL FIRST CLASS SEWING MACHINES can be had at favorable rates to the purchaser, if ordered soon, from the Grangers' Business Association, N. E. Cor Davis and California streets, S. F.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Reel Ponds and Skating Rink.

SUCCESSFUL IN EVERY CASE.The following letters, from practical men who have used this machine, will show to
those interested what it has accomplished:BANDERETA MINE,
Mariposa County, Feb. 7th, 1876.CHAS. SCHOFIELD, Esq.—Dear Sir: We have been using your Concentrator at our mill
about six months, and find that it saves over 90 per cent. of the sulphurets contained in the ore,
and all of the amalgam and quicksilver which escapes from the battery. The machine is simple
in construction, perfect in operation, and requiring no power to run it, is very economical. I
can confidently recommend it to all mill men as the best and cheapest Ore Concentrator now in
use.
Yours respectfully, LEVI NOEYS, Superintendent.NONPAREIL GOLD MINING CO.'S WORKS,
Deer Flat, Tuolumne County, Cal., April 12th, 1876.MR. CHARLES SCHOFIELD—Dear Sir: It is four months since the Sulphuret Concentrator
you furnished our company's mill with was first put in operation, and during the past three
months has been nearly in constant use. The men attending the Concentrator having acquired
by practice a thorough knowledge of its workings, there is nothing more to be desired; it is
perfect. A number of mill men have examined the Concentrator and its workings, and pro-
nounce it the most simple in its construction, perfect in its work, and cheaply run of any they
had seen. If you think by showing this it will assist you in disposing of your Sulphuret
Concentrators, you are at liberty so to do, as it will afford me much pleasure in having contri-
buted my little mite towards rewarding true merit. Hoping you will meet with complete success,
I remain yours truly,
JOS. J. DuPRAT, Superintendent.CON. ALABAMA M. CO.,
Tuolumne County, May 1st, 1876.C. SCHOFIELD, Esq.—Dear Sir: The Concentrating Machine recently purchased of you is
now in active operation, and we are highly pleased with it. It saves over 90 per cent. of our
sulphurets, and is run with very little expense. We could not afford to be without it, and can
safely recommend it to all mill men as the best and most economical machine in use.

M. S. MCCONNELL, Superintendent.

WASHINGTON MINE,
Mariposa County, Cal.CHAS. SCHOFIELD, Esq.—Dear Sir: Having had one of your Double Rigged Concentrators
in use now at this Mill for over a year, I take this opportunity of informing you that it is far
superior to the old English Buddie we have been using for the last four years, not only in a
saving of labor, but having a less waste of sulphurets in washing.We have the machine connected with the tail sluice, and receives the sand and water direct
from the batteries, without any handling, and it does the concentration for the 20 stamps easy,
with a loss of less than 10 per cent.Two Chinamen do all the work required—one night and the other day—working 12 hours
each, and get out about a ton each day, thus concentrating 30 tons into one, at a cost of less than
four dollars. As the cheapest, most economical and best working Concentrator I know of I can
recommend it to others without any hesitation.Yours truly, GEO. E. WEBBER, Jr.,
Superintendent Washington Mining Company.MR. SCHOFIELD—Dear Sir: Having carefully examined your Concentrator, which I have
seen in successful operation at the Francis Company's Mill and also at the Benton Mills, on
the Mariposa Estate. I have no hesitation in saying that it is the most valuable Concentrator
I have met with during my long experience as amalgamator in this country. Its manner of
catching quicksilver and amalgam is thorough and complete, and it saves the sulphurets clean
and with a loss of less than ten per cent.

Yours respectfully, L. BURDOW.

MR. C. SCHOFIELD—Sir: I have worked one of your Sulphuret Machines at the Benton
Mills about 30 days, and am satisfied it is the best machine for saving amalgam and sulphurets
ever used on the Mariposa Estate.

L. GILMAN.

The following testimonial is from the well known mining expert, PROF. J. E. CLAYTON:

CHAS. SCHOFIELD, Esq.—Dear Sir: Having followed the business of mining engineering
for upwards of 30 years, and having had in this connection much to do with regulating ma-
chinery for saving gold and concentrating sulphurets, and having in nearly every mining camp
on the Pacific Coast examined the various kinds of Ore Concentrators in use, I will say that I
have nowhere seen anything half as cheap and simple in its construction, scientific in principle
or effective in operation as your machine.

J. E. CLAYTON.

Machines can be Furnished at Short Notice. In all Cases we Furnish the
Concentrator Complete, Set it Up, and Instruct the Buyers as to
the Proper Way of Managing It.

EXPLODERS.

HASKINS' BLOWING ENGINES

For Mines.

Large Assortment of

MORSE TWIST DRILLS.

HASKINS' PORTABLE HOISTING ENGINES, constructed especially for economical use in mining districts, with Compressed Air or Steam, adapted to all classes of underground work and made throughout on the interchangeable plan, so that all parts can be duplicated when desired. Catalogues and Estimates given on application.

THE BUCKMINSTER ROCK DRILL.

The Most Efficient Rock Drill in the Market.

LIGHT, STRONG and DURABLE.

No External Machinery Liable to Injury from Rough Usage, as all the Working Parts are Enclosed in the Cylinder and Valve Chest.

A TRUE SMOOTH HOLE EVERY TIME. THE MOST ECONOMICAL DRILL YET MADE.

THE WORKING PARTS OF THE DRILL ARE FEW AND SIMPLE IN ARRANGEMENT, SO THERE IS NO LIABILITY

OF INJURY. THE CLAMPS FOR HOLDING THE DRILL ON THE TRIPOD, FOR HOLDING

THE DRILL TOOL IN POSITION, AND FOR FIXING THE WEIGHTS

ON THE LEGS OF TRIPOD, ARE ALL IMPROVED

AND VERY EFFECTIVE.

The device for rotating this Drill has few parts, and can not get out of order. There is no chance for wear. The motion is positive, and never falls of action. The Drill Carriage can be turned clear round the column, and can also turn in a complete circle on the head of the clamp.

All parts subject to wear are of the Best Cast Steel, and all made to gauge and interchangeable.

This is the Lightest and Strongest Rock Drill yet invented. Being nearly all Cast Steel, it is easily handled and moved, as all superfluous metal is dispensed with.

We also call the attention of those interested to the Horizontal Air Compressor furnished with the Buckminster Drill when desired. It is Economical, Light, Easily Run and conveniently portable.

We claim that the Buckminster Drill will do as good work as any in the market, at a much less expenditure of power, and a great decrease in first cost of machinery. Drills made all the usual sizes.

Mining Companies Desiring Rock Drilling Machinery should Examine this Drill and Air Compressor, and we are confident that it will give satisfaction. Address,

SAN FRANCISCO, SATURDAY, JUNE 10, 1876.

VOLUME XXIII
Number 24.

The Paul Process.

We have not spoken of late of the "Paul dry process," for the reason that we desired to obtain an illustration of the machinery, so as to show the details of working, and also because it is only now that Mr. Paul is willing to show the designs of its mechanical construction. The mill is automatic, and all crushing, pulverizing and amalgamating is done dry—water only being used for separating the amalgam and mercury from the ore and washing the debris off.

The plan of Paul's dry process mill for working gold and silver ores, is shown in the illustration on this page. By referring to the cut the details may be understood. 1 shows the position of calcining furnace; 2, the self-feeder; 3, the stamp battery; 4, dust casing; 5, elevators (these are not used when the ground admits of the battery being set on a level with the pulverizing barrel); 7, hopper for pulverized ore; 8, amalgamating barrel; 9, hopper for conveying ore to the settler; 10, first settler; 11, amalgam sse; 12, hydrostatic settler; 13, concentrator.

The ore is reduced to powder by attrition of quartz, and the amalgamation is speedy. Ore is passed into self-feeders, and that is the last of the handling. The gold contained in it will be found in the amalgam safe (which we illustrated two weeks since) all ready for retorting. The machinery is ingeniously constructed and works effectively. It is rendered perfectly automatic, so that from the moment the quartz is put into the feeder until the gold comes from

The Bonanza on Bernal Heights.

Our contemporaries have taken notice of the alleged discovery of a gold bearing ledge on Bernal heights, and did consider the matter half in earnest. The mine being so close at home and rumor spreading to the effect that active measures were taken to organize and develop the location, the expert of the MINING AND SCIENTIFIC PRESS repaired to the ground to make an examination and duly report to the public. After considerable hunting on the hills at the head of Folsom street, a hole of about 10 feet in depth was discovered, supposed to be a shaft sunk on the bonanza. But this was sufficient to give us a clear idea as to the formation of the famous lode.

Taking all facts into consideration we can readily pronounce the whole matter

A Fizzle.

The origin of metal discoveries in that vicinity arises from the fact that several pieces of fine silver and gold ore were found in a well which was being deepened. The owner of the place got so excited about it that he found it necessary to quiet his high spirits by a three days' indulgence in low spirits, but an indiscreet insider informed the

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency the following are worthy of mention:

WELL BORING DEVICE.—John Milton Creal, Los Angeles, Cal. The object of this invention is to provide certain improvements in apparatus for boring, and it is more especially applicable to the sinking of artesian wells. It consists of a heavy cylinder through which the

the sugar. By this mechanism the inventor does away entirely with the cumbersome arrangement of rods which must be joined and separated every time an ordinary auger is put down or withdrawn and are objectionable also on account of their weight. Their size causes an overflow of water when put down, and when drawn out if there is quicksand in the well the pressure of water to restore an equilibrium forces the sand in so as to practically stop operations. This is avoided by the use of the rope, which being only three-fourths or seven-eighths inches in diameter will not cause any overflow, and the cylinder will retain all

PLAN OF PAUL'S DRY PROCESS FOR WORKING GOLD AND SILVER ORES.

the machine in the shape of amalgam, the stuff is not handled.

Mr. Paul has given many years of study to the scientific manipulation of ores and mechanical construction of this mill, as simple as it looks. The simplicity of the mill and the cheapness with which Mr. Paul says he can work the ore must make it desirable. Only two men are necessary to run a 10-ton mill. A mill of this pattern is now being erected in this city, for the purpose of proving to those interested in mining all that Mr. Paul has claimed, and where parties can get all the ore worked that will be necessary to make the practicability of the mill acceptable. It will be open to the close inspection of the most critical. Mr. Paul's experience in these matters covers some 25 years on this coast, and he is not one to claim more than he knows he can accomplish.

The pulverizing barrel, which is one of the important features of this process, and which pulverizes quartz with quartz, and receives the ore, delivering it automatically, we will illustrate in a future number of the PRESS. Mr. Paul has just issued a pamphlet, which gives the process more in detail than we have the space for, and any of our readers who desire further information can receive one of these pamphlets by addressing Almarin B. Paul, room 20, Safe Deposit building, San Francisco.

THE CALIFORNIAN is the title of a new 32 page monthly started in this city by E. I. Johnson.

unfortunate millionaire-in-prospect that the simple reason for such ore being found there was because it was put there, and the sobering up was instantaneous. Still the story was carefully preserved by all concerned, and the rumor of vast treasures being hidden in those hills got around the whole neighborhood, and prospecting on Sundays or moonlight nights was frequently indulged in. A number of holes from six to 18 inches in depth give proof of the vigorous prosecution of the work, but to no effect.

To an illustrious foreigner, Mons. Victor Ressayre, the honor was reserved to discover the supposed lode. San Francisco and the world generally were astonished at the announcement, all the tails in the vast Chinese empire commenced to wag, several banks busted—and Bismarck retired to Varzin. But, alas, they have all recovered. The ten-foot hole gives sufficient evidence that there was but a small piece of a barren quartz ledge floated there; that passed, no more quartz would be found nor may he for—a long time to come.

TUOLUMNE REUNION ASSOCIATION.—The old residents of Tuolumne county, and their friends, will hold an annual picnic at Badger's park, Oakland, Saturday, June 17th. An inviting programme of musical and literary exercises is announced.

stem passes and carries at its lower end a boring tool. Above the weight this stem is twisted so as to form a right hand spiral for a short distance, and then a left hand spiral for another short distance. A weighted cylinder encircons this double spiral and runs at each end fits the spiral so that when the cylinder is drawn up the stem and tool will be revolved, and when it is let down the action is repeated by the other spiral so that it is continuous. Ratchets and pawls surround each nut so as to prevent the stem from rotating backwards, and pawls upon the lower weight prevent it from rotating. The upper cylinder is simply operated by a rope from the top of the well. A cylindrical bucket, open at both ends, surrounds the stem above the boring tool and thus receives the earth bored and brings it to the surface. The operation is as follows: The cylinder being alternately raised by the rope and allowed to drop back again by its weight, will turn the stem both in rising and falling with a continuous motion, by means of its contained mechanism and the right and left spirals upon the stem. The weight of the cylinder exerts a continuous pressure upon the boring tool, causing it to enter and take up the earth, which is retained in the hollow cylinder until the latter is filled, when the whole apparatus can be withdrawn and emptied by simply winding the rope upon a windlass. Simple devices prevent the cylinder from turning with

the earth or sand, so that whatever is bored out can be drawn up to the surface.

TRACE FASTENER.—William Quinlan, Mayfield, Santa Clara Co. A very common method of preventing traces from slipping over the heads of such pins as are usually secured to the ends of singletrees for vehicles of all descriptions has been to pass a thin strip of leather through an opening formed in the head of such pin. This, however, is open to the objection that the leather is extremely liable to rot and break off; and it is the object of the inventor to obviate such objectionable feature, and to provide a simple, durable and effective means whereby the traces can be easily secured in place and all liability of accident avoided. To this end the invention consists substantially in a spring catch plate, which is pivoted to a bent arm connected with the end of a singletree, and arranged to engage with the pin upon which the trace is held.

The annual meeting of the American Institute of Mining Engineers was held at Easton, Pa., on May 23d, and the following officers elected: Abram S. Hewitt, President; W. P. Blake, E. B. Cose and R. W. Raymond, Vice-Presidents; R. W. Hunt, J. S. Newberry and T. F. Witherbee, Managers; T. D. Rand, Treasurer; T. M. Drawn, Secretary.

The Trial of Agricultural Machinery at Stockton.

[J. W. RILEY in Rural Press.]

On my arrival in Stockton on Saturday, May 13th, I went to Washington square, where I found assembled a large number of farmers, to witness a trial of straw burning engines and other agricultural machinery. Among the numbers present were Mr. Ames, of the Ames engine manufacturing company, Oswego, N. Y.; Mr. Hamilton, of the firm of Baker & Hamilton, San Francisco; Mr. Rice, of Haywards, manufacturer of straw burning engines; Mr. Clark, of San Jose, agent for Mr. J. Enright, of San Jose, manufacturer of straw burning engines; Mr. B. Jackson, of Woodland, patentee of the Jackson self-feeder for threshing machines. The following named Stocktonians were on hand to exhibit and explain their respective implements: E. J. Marsters, self-feeder; Thomas Powell, electric elevator; Mr. King, straw burning attachment; Matteson & Williamson, derrick forks; H. C. Shaw plow company. The above named manufacturers, agents and patentees took a lively interest in showing off the good points and advantages of their respective wares.

King's attachment claims superiority and preference over all others on account of its adaptability to all styles and patterns of wood or coal burning engines, to which it can be fitted for about one-fourth the cost of changing to the Cornish style of boiler. The straw is fed through a tube to the fire box. The grate bars are three or four inches apart. In front of the tubes a concave plate is arranged, similar to the brick arch used in locomotive boilers. This plate, to a great extent, prevents the choking up of the tubes, and ensures a more perfect combustion of the straw. With this attachment on a Gaar, Scott & Co.'s engine, the steam gauge indicated 100 lbs. pressure to the square inch, 50 minutes after starting the fire, with two gauges cold water. For a more detailed account of the performance of this engine, the reader will refer to your advertising columns. This engine ran a burr mill grinding barley. Fire box boilers for burning straw are manufactured extensively in England for shipment to Hungary and other grain growing countries where straw is of little or no value.

The Rice engine was running a gold medal separator with E. J. Marsters' self-feeder attached. Several loads of barley were threshed, which had been hauled into town for the purpose of showing the working of this engine, self-feeder and separator.

The Enright straw burner, represented by Mr. Clark, was not on the ground, but a large engraving (framed) for convenience of showing the engine served to give any one a correct idea of the engine, in connection with Mr. C.'s explanation showing its improvements on the first ones made. The engine is a bed plate hoiler, felted and covered with galvanized iron and bands. After this exhibition I noticed three of the Enright engines on one freight train. The demand for these engines will probably exceed the supply this season.

Byron Jackson, of Woodland, proprietor of machine shop and planing mill, was on hand to show his self-feeder and elevator for threshing machines. For four years Mr. Jackson has made and sold 200 of these labor saving attachments; six of them are on the Glenn ranch, Colusa county. One of these feeders is attached to the 48-inch threshing machine "Monitor," illustrated on first page of the Rural Press some weeks back. Mr. Jackson now has over 60 orders for his feeders. He employs 26 men, and manufactures horse forks and derricks and Wm. Jackson's grain lifters, and runs a steam threshing machine. He has fitted to his portable engine a traction gear. This engine will move itself and separator and derrick wagon. This all our engines ought to do and eventually will do, though at the present time I believe there is only one other engine in the State that will do this. The next improvement is to apply King's attachment for burning straw to this engine, which will be done before threshing commences. A straw burning traction engine with windlass to hoist forks by steam, will save six horses and one man, and one cord of wood per day, and the Jackson feeder saves one man at \$4 per day.

E. J. Marsters, of Stockton, manufactures a self-regulating feeder for threshing machines. This feeder is new. It gave good satisfaction last year. The manufacturer claims to have the best feeder. They are very simple and light weight, about 175 pounds. They do not require detachment from the separator when moving, and save the labor of two men. By removing the feed board, it is secured in position without cutting away or altering the separator. It requires but little power to run it and has no complicated parts to get out of order.

Thomas Powell's electric elevator attracted much attention. This elevator is used in the harvest field to elevate grain, hay and straw from the wagon bed to the stack. The load is taken up in a center-opening net and raised by horse power with a suitable derrick. The stack can be built of great height and the tramping out of grain is avoided. The header is not delayed for want of a wagon, as a four-horse load is transferred to the stack in a few seconds. By referring to your advertising columns, the reader will get a fair idea of the elevator.

Study of American Mines and Metallurgical Works by Foreign Engineers.

The following announcement of the officials sent to the Centennial exposition has been communicated to the *Engineering and Mining Journal* through the American Institute of Mining Engineers:

Russia sends Collegienrath Prof. Nimolsy and Hofrath Prof. Jossee, Hofrath Skskoffsborg, Secretary of the Corps of Mines.

The German commission will be made of two sections, which will study separately the Eastern and Western mining regions. The Eastern section, for the study of our coal mining, will be conducted by the mine directors, Brossa from Zabrze in Upper Silesia, and Hornecke from Saarbruck; iron and lead works in the East by Bergrath Dr. Weddig; mining and furnace machinery by Oberbergrath Althaus from Breslau; transportation and the questions of trade and labor will be studied by Mine Assessor Mosler, of Berlin.

The second or Western section takes up the subjects of ore mining and metallurgy, which will be studied by Mine Director Koch, of Tarnowitz, in Upper Silesia, and Mine Assessor Richter, from Clauchal, in the Hartz.

The reports of these distinguished mining engineers and metallurgists will undoubtedly be of great interest and value.

Why does not our Government appoint commissioners to report upon mining and metallurgy as exhibited at the Centennial exposition?

An Ingenious Workman.

An Osklend mechanic has prepared to send to Philadelphia a mammoth seal of the State of California, composed of no fewer than thirty-five of the native woods of the Pacific coast. The design is novel and excellent and the workmanship elaborate and delicate. There is first the outline of the body, wheel-like in shape and four feet and four inches (in diameter and twelve inches through the hand from front to obverse side. The frontispiece, if we may term it such, is suggestive. The groupings of figures are most artistically done, and the carving of each figure, of mountain, of water, of ships, most ingenious and faultlessly executed. The prominent figure is "Minerva," in standing posture, two feet six inches in length by seven inches in width, and seven inches through, the whole, being made of white cedar. A conchont grizzly bear occupies a prominent position at the foot of the goddess. The harte is fifteen inches in length, seven and a half inches in width and four inches through his ebagg mane head. The wood used in the building of the bear is laurel. A very unique and suggestive picture is that of the miner with raised pick, board at foot, and bank of earth above. He is six inches tall; his head and shoulders are of chips of California holly; mountains of tiger wood, and sheaves of wheat of yellow pine. The carved capitals "E. U. R. E. K. A." are made of the tamar wood. The segment rim with stars is of red cedar, and the back representing the sky of sugar pine. The man's body and legs are of black gum; his pick is of pepper wood, the rocker by his side of mesquit, the shovel blades of tit-ti, the handle of willow, the dipper of myrtle, the pan of mountain mahogany, the rooks of live oak, and water of California maple. The spear handle, which the goddess Minerva holds in her hand, is made of the gray mesquit, and 17 inches tall; and the spear itself, made of aureola. The shield is very elaborately wrought from the aureola, stars of willow and stripes of elder. The scroll in the eagle's mouth is of redwood, and capitals, "WELCOME," of California orange. A handsome plate, with the figures, "1876" cut from the California huckeye, and the scrolls on the end of the plate are made of the wild cherry. There is a motto "With Freedom for All," elegantly carved from the tule wood. Around the rim the motto in capital letters is conspicuously seen, i. e., "The Great Seal of the State of California." This is made of orange wood.

The back of the wheel is scarcely less elaborate and quite as tasty as the front. The center picture is a magnificent eagle, carved from the tiger wood. It is twenty inches long, nineteen inches across the body, with wings forty five inches in dimensions. The rim is of redwood root veneer, the molding of California walnut, and the inner molding of orange wood. The motto "Liberty and Independence," is displayed conspicuously. The first word is carved from the myrtle, the second from live oak, and the word "Independence" from the myrtle. Then there is a scroll made of Spanish cedar, and the main background of sugar pine.

The pedestal on which the main seal is to stand is three feet four inches by 13 inches. Its various sections are made of mahogany and cedar, the molding of walnut, and the scroll on top of walnut.

The table on which the two other pieces are to stand are manufactured of the tumane wood. The top is of walnut. Its dimensions are four feet 11 inches by two feet four inches. The legs are ornamented with beads, flutes and leaves. There are four drawers of walnut in the table, which is a model of beauty.

The ingenious mechanic who devised and manufactured this remarkable specimen of handiwork is Charles J. Larson, one of the employees in the mills of Messrs. Burnham & Standeford. He has collected and assorted all the woods, and done all of the mechanical labor. He has spent all of the last five months in perfecting this monument of his skill and industry.—*Oakland Transcript*.

Abolishing Telegraph Poles.

In accordance with the plans adopted some time ago by the Western Union telegraph company, work was begun early yesterday morning, nearly opposite the Western Union telegraph building, preparatory to laying four underground tubes, two for electric wires and two for pneumatic carriers.

The trench which is being opened will be three feet deep, and when the tubes are laid down the wires will be drawn through. There will be but a few at the outset, but they will be gradually increased up to 125 should business require it. Two brass pipes will be laid through Broadway and Wall streets to No. 14 Broad street, and two through Maiden lane to No. 134 Pearl street, and from there to the Cotton Exchange, for pneumatic carriers. Iron pipes will be used for the wires. There was for a time some hesitation in the mind of Mr. Prescott, electrician to the Western Union telegraph company, as to the metal to be used for the pneumatic tubes. In London lead is used; in France and Germany, iron. The company has, however, decided to use brass. One of these tubes will convey messages from the main office; the other will bring the messages to it. The pipes will be perfectly smooth inside and air-tight.

The courier in which messages are inclosed is a gutta percha pouch, covered with felt, two inches in diameter, with a band of felt projecting half an inch round the end. This fits the pipe accurately, and is driven to its destination by compressed air. By the action of another exhaust the pouch is brought back. Each of the offices is supplied with two pipes, to prevent interruption and allow the passage of a continuous stream of pouches. Each pouch has a capacity for 50 messages, which are kept in place by a rubber band. The time occupied by the passage of a pouch is half a minute. The underground wires will be conducted through three iron tubes resembling common gas pipes. The manner of introducing the wires through the pipes is as follows: During the work a wire is run through each section of 400 yards. A box containing coiled wire is then drawn through the next sections of the line. The pipes have a capacity for 125 wires, but only 100 will be placed in them. In the building a new duplex pump has been placed to furnish motive power to the pouches passing through the pneumatic tubes. The whole work is under the direction of Mr. A. S. Brown, Superintendent for this division, and will be finished within a month. The President of the company says that the new system will save operating expenses and facilitate the handling of messages.—*New York Herald*.

Washing with Hard Water.

"Tids", in a recent number of the *Farm Journal*, asks what is the best way of washing clothes with hard water. There are various substances and preparations advertised, to soften water, but the very best I know of, and I have tried many, is to "break" with wood ashes, by the old way of scalding sufficient ashes and then turning ashes and water into a barrel which has been filled from the well. It is better to have it done over night before using to wash, that it may thoroughly settle, and then use care in dipping off. If I were obliged to use hard water, I would have a good barrel with a spigot near the bottom for drawing the water off, as the least of the sediment or ashes makes the clothes yellow. The quantity of ashes needed to cleanse a barrel of water can only be determined by trial, as in different soils and localities the quality of the water varies. In coal burning regions, where good wood ashes is hard to get, a washing fluid made of unsalted lime one pound, sal soda two pounds and borax one pound, will be found very good. To prepare, boil the lime in one gallon of water, the soda and borax together in another gallon, turn them together in a vessel and when settled draw off the clear fluid, and fill up with another gallon of water, which when clear, add to the first and cover, or cork in jugs for use, using just enough to soften the water. This is an excellent preparation for use, even with soft water, saving soap and rubbing, and whitening the clothes without injury.

PATENT HORSE AND CATTLE GROOMER.—During the past month Mr. N. Wilson has practically demonstrated the value and capabilities of an ingenious grooming apparatus at the agricultural hall, Islington. Briefly described, the invention consists of a brush somewhat akin to the rotary hair brush now in use in hair dressing establishments, and is operated at the extremity of a suitable spindle attached to a series of jointed rods, fitted with a new hemispherical form of joint in such a way that it is capable of being worked by an ordinary fly-wheel, which can be managed by a lad. The apparatus is also arranged to work either right or left, so that both sides of the horse can be brushed nicely and thoroughly, penetrating the coat of the animal in such a way as to effect a complete grooming, while removing all dirt and secretions without irritation or inconvenience, and imparting to the coat that glossy appearance which is held to be the true test of good grooming. The advantages of such a groomer must be apparent, for, besides performing its work so satisfactorily, much time is saved, which is a point of merit unattained by any of the old methods of brushing and curry-combing, and as there is nothing in the operation to worry or hurt the animal no difficulty is experienced, even with horses of nervous temperaments.—*Ironmonger*.

Bill to Restrict Chinese Emigration.

WASHINGTON, May 15th.—Senator Sargent introduced to-day the following important bill to restrict the emigration of Chinese to the United States:

Be it enacted, etc., That no master of any vessel owned in whole or in part by citizens of the United States, or by citizens of any foreign country, shall take on board such vessel at any port of the Chinese empire, or at any other foreign port or place whatever, any number exceeding ten Chinese passengers, whether male or female, with the intent to bring such passengers to the United States, or shall bring such passengers within the jurisdiction of the United States.

Sec 2. Whenever the master of any such vessel takes on board of the same at any foreign port or place any greater number of Chinese passengers than is prescribed in the first section of this Act, with the intent to bring such passengers within the jurisdiction of the United States, he shall be deemed guilty of misdemeanor, and shall, for each passenger so taken on board and brought within the jurisdiction of the United States exceeding the number of ten, be fined \$100, and may also be imprisoned for a term not exceeding six months.

Sec 3. The master of any vessel arriving in the United States, or any of the Territories thereof, from any foreign place whatever, at the same time that he delivers the manifest of the cargo, and if there be no cargo, then at the time of making report or entry of the vessel pursuant to law, shall, in addition to the other matters required to be reported by law, deliver and report to the Collector of the District in which such vessel shall arrive, a separate list of all Chinese passengers taken on board of his vessel at any foreign port or place. Such list shall be sworn to by the master in the same manner as directed by law in relation to the manifest of cargo, and on the refusal or neglect of the master to comply with the provisions of the section he shall incur the same penalties, disabilities and forfeitures as are provided for refusal or neglect to report and deliver manifest of cargo.

Sec 4. The amount of the several penalties imposed by the foregoing provisions, shall be a lien on the vessel violating these provisions, and such vessel shall be libeled therefor in any Circuit or District Court of the United States where such vessel shall arrive.

Sec 5. Informers shall be entitled to one-half of any penalty or fine collected under provisions of this Act, upon their information.

Sec 6. Nothing herein contained shall be held to repeal or modify any law forbidding the importation of coolies or of females for immoral purposes into the United States; provided, that no consul or consular agent of the United States residing at any port from which any vessel carrying Chinese passengers may take her departure, shall grant the certificates provided for in Section 2162 of the Revised Statutes, for more than ten Chinese passengers on any one vessel.

Sec 7. This Act shall take effect from and after the 1st of September, 1876.

SWEET YEAST.—As many housewives have trouble in this climate in keeping their yeast sweet and good, they will be glad to learn how they can at all times have good reliable yeast that will keep for weeks, and which makes good, light bread. Yeast made after the following recipe will never fail, if the directions are followed: Take a small handful of hops and boil in a quart of water for half an hour, or until the hops become sticky. Strain off the liquor and let it cool somewhat, add then a teaspoonful of sugar and two even teaspoonfuls of flour, and pour into a stone jar of pitcher and cover with a cloth. Let this stand three or four days, when it will be ready for use. When bread is to be made, peel and boil four or five medium sized potatoes, and when done mash them and add to the pulp enough of the water in which the potatoes were boiled to reduce it to a batter; add two teaspoonfuls of flour, one of sugar, and a good half tea cup of the hop mixture, mix and set as ordinary yeast. It will take six or eight hours to raise. Use as ordinary yeast. The hop liquor will make good bread; but it is best to add the potatoes, as they keep the bread from becoming too dry. This recipe is worth ten dollars to any housekeeper.—*Santa Barbara News*.

THE AMERICAN SOCIETY OF CIVIL ENGINEERS.—A circular has been issued by G. S. Greene, President, and G. Leverich, Secretary, of the American Society of Civil Engineers, in relation to certain tests of iron, steel and other metals proposed by the United States board appointed for that purpose. The society have a 400 ton testing machine, nearly finished by superior workmen, of the best materials. Also, a chemical laboratory for a comprehensive series of comparative chemical and physical analyses and tests of irons, steels, bronzes—subjecting them to a variety of stresses to ascertain their real strength so as to avoid the present excess of material, and cheaper structures and machinery, and also to make the production of machinery a matter of scientific synthesis rather than a trade secret. To carry out this system of gaining essential information that cannot be obtained in any other reliable way, considerable expense will be incurred, to meet which a small appropriation is asked of Congress—a sum that should be promptly given, as it would save the heavy charges for experimental boiler tests, etc., which, as yet, have been unsatisfactory, though they have involved large expenditures.

MECHANICAL PROGRESS.

Locomotive for Working Steep Gradients.

An English engineer, Mr. Andrew Handyside, has recently patented in England and this and several other countries a locomotive engine for drawing trains up inclines. A trial was recently made with one of these engines at Bristol, England, and the result was such as to show that the invention is one of some merit.

The engine weighed 13 tons, and to it were attached two trucks weighing together 25 tons, 14 cwt.; and one portion of the line on which the trial was made was on an incline of one in twelve. The peculiarity of the system is that the engine is coupled to the train by a steel chain or wire rope, wound round a drum mounted in the framing of the engine. The axis of this drum works horizontally in bearings fixed in the main framing of the engine, and it is rotated by gearing from a separate pair of cylinders, distinct from the usual cylinders which drive the locomotive. A drum, two feet in width and one foot in diameter, will accommodate chain enough to fulfil all the requirements of the system. On each side of the engine framing, and on each side of one or more carriages or wagons of the train, there are suspended one or more self-acting gripping struts, which, when let down on the rails by the driver or other person in charge of the train, will firmly grip the sides of the rails, and hold the engine or train stationary. On arriving at the foot of the incline, the engineer releases the hauling drum, and, without stopping the engine, runs up the gradient to the required distance. The struts are then let down on the rails; and by grasping the rails, they render the engine stationary, and the load is drawn up to the engine much after the fashion that loads are drawn up inclines at collieries. The last truck of the trial train was furnished with an automatic gripping strut, which, when the trucks commenced a retrograde movement, at once grasped the rails on each side, and held the train in its place beyond the possibility of its being moved, on informant states, even when the engine with full steam on was backed against it.

The experiments were of the most thorough description, and the invention was tested in every way. In the first place the value of the gripping strut was shown. The powerful little engine mounted the gradient without its load, and, full steam on, ran the whole length of the siding. At a signal from Mr. Handyside, the brakes were applied, and the engine was brought to a standstill in the length of a rail and a half. The contrast between the power of this brake and the ordinary hand brake, with which the engine was also supplied, was fully shown. The wagons were then attached, and the brakes on the engine and on the brake van were applied simultaneously with equally satisfactory results. This experiment was witnessed with considerable interest, as the brake question is just now occupying very much of the attention of railway men. With the continuous brake, it was pointed out that, 90 per cent. of the wheels being braked, a train is pulled up in about 900 feet with the train going at a speed of 50 miles an hour. In this case, the train pulled up in about 600 feet, and only 75 per cent. of the carriages were braked. After duly testing the brake, the method of mounting steep gradients was shown. The engine put full steam on, ran to the foot of the incline, and then, letting out the steel wire rope which coupled it to the trucks, mounted the steep alone. The gripping struts were then let down; and the engine having thus been made stationary, the trucks were hauled up to it, the automatic gripping strut coming into action, and the whole train remaining stationary. The accomplishment of this test occupied a surprisingly short time. The tracks were then lowered to show the control which the driver was able to exercise over a train for lowering purposes. The company claim that, by this invention, smaller and less powerful engines may be used on heavy gradients, and that it will allow of less cost in constructing lines, inasmuch as less cutting will be required. — *Scientific American*.

TELEGRAPH WIRES AND INSULATORS.—The wire mostly employed in England for telegraph work is of the quality of soft iron wire, known as "best best." There appear to be some ridiculous names of iron wire, as there are of plates and bars; there are best, best best, and extra best best, and charcoal wire, the best of all. Surely the makers or the merchants, or whoever gave these names to wire and other forms of manufactured iron, cannot reflect with any pleasure upon the occasions which have given rise to these pretended superlatives and super-superlatives, ridiculous as they are in every other sense than that of enabling manufacturers to gain some temporary advantage over the public and over each other. It would appear that "best" wire is not good enough for telegraph purposes; for, in testing the strength, the scale begins with "best best," and goes on to include the two higher qualities. The material from which most of the insulators employed at the present day in England are formed is brown earthenware. It does not insulate so highly as porcelain, nor can it be so perfectly glazed; but it is produced with greater uniformity of quality, and its manufacture can be more thoroughly relied upon, and it possesses the farther advantage of cheapness over porcelain, ebomite, or glass. — *Builder*.

Mechanical Puddling.

In *Harpers' Annual Record of Progress*, for 1875, we find the following: The problem of mechanical puddling attracted more attention during the past year than ever before, although the results obtained in the different manufacturing districts into which rotary puddlers have been most largely introduced are somewhat conflicting, from which it would appear that the problem of puddling by machinery has not yet been wholly solved. In certain quarters of England, and in Pittsburg in this country, the Danks furnace has given great satisfaction, and the number of furnaces has been increased. In certain other districts the experience with this system has not been so fortunate, while the Crampton system has been very successfully operated.

In England, where comparatively greater activity in the manufacture of iron during the past year prevailed than in this country, the Crampton system, in this special field, appears to have been steadily gaining in favor. In our brief allusion to the Crampton plan, in last year's *Record*, we noticed that its chief features resided in the adoption of a water jacket arrangement and the use of dust fuel; and it is very suggestive to note that in certain modified Danks furnaces, lately erected in England, the leading improvement consisted likewise in the introduction of a water jacket arrangement—approximating therefore in construction to the Crampton furnace so far as the mode of cooling by water is concerned. So far as relates to the speed of working, both systems appear to be equally good, provided the apparatus is in good condition; but in the quality of endurance under the rough usage of practice, which in this case happens to be the test of commercial success, the friends of the Crampton system lay claim to decided superiority. With regard to the relative merits of the latter system and the modified Danks furnace, just referred to, a competent authority speaks as follows: "As to what would be the relative endurance of two furnaces, each constructed on Mr. Crampton's plan, with water jacket arrangements, but one worked on the Danks system and the other with dust fuel, there are no data for actually determining; but there are certainly no reasons for believing that the results would be in favor of the former." And the same authority sums up a comparative resume of the subject in these words: "Altogether, when we consider the numerous advantages attendant on the use of fuel in the form of dust, and the general excellence of the mechanical arrangements which Mr. Crampton has designed and practically carried into effect for the utilization of such fuel, we cannot but regard the Crampton furnace as the most advanced solution of the problem of mechanical puddling." On all hands, finally, it is admitted that the ultimate success of mechanical puddling is assured, and that the puddling process of the future will be carried on in rotary furnaces capable of dealing with large charges, and worked in connection with plant capable of easily manipulating the large puddled balls produced.

KEEP OFF THE RAILWAY TRACKS.—An important and interesting opinion was recently delivered by Judge Paxson, of the Supreme court of Pennsylvania, in a suit involving the right to recover damages for injuries received by the claimant at a time he was walking upon a railway track. The decision is noticeable on account of its clear assertion of the doctrine that a railway company has a right to the exclusive use of its own tracks, except at crossings, and that any person who violates this rule thereby not only forfeits all claim to damages for injuries that may be inflicted upon himself, but commits what is in England regarded as a penal offence, and should be so considered here. The opinion very forcibly and justly says: "We hold these corporations to a strict line of responsibility whenever passengers are injured by accidents to their trains. It follows that we should be equally emphatic as to their control of their tracks. Except at crossings, where the public have a right of way, a man who steps his foot upon a railroad track does so at his peril. The company have not only the right of way, but such right is exclusive at all times and for all purposes. This is necessary, not only for the proper protection of the company's right, but also for the safety of the traveling public. It is not right that the lives of hundreds of persons should be placed in peril for the convenience of a single foolhardy man who desires to walk upon the track. In England it is a penal offence for a man to be found unlawfully upon a railroad track. It would add materially to the public safety were there a similar law here."

RUSSIAN MANUFACTURES.—The Russian edge tools differ from those of other countries in some peculiar respects. The common spade, for instance, is made chiefly of wood and simply tipped with iron; it is of small size, rounded at the edge, and has a plain carved handle. The axe is much larger than that manufactured by other nations, and is used, too, for all kinds of carpenter's work—an ax, in fact, as a plane, a hammer, and even as a saw, the last tool being rarely used by the Russian mechanic, for he can wield the axe more easily, and cut through thick logs of wood with incredible precision and rapidity. Samovars are a leading article of the Russian metal industry, these being a kind of tubular boiler, with little charcoal furnaces, and are used for making tea; the material is copper,

which is almost exclusively used among the well-to-do classes for cooking utensils, tinware, hollow cast iron vessels and pewter being but little in vogue. Horseshoes are produced by hand at the rate of some thirty million annually. Bell making is carried on with especial success, the bells being remarkable for their immense size and richness of tone. Harness fittings of European pattern are made, but only in very limited quantities, those which are used upon Russian harness being of considerably different construction.

SCIENTIFIC PROGRESS.

The Work of the United States Fish Commission.

Professor Spencer F. Baird, United States Commissioner of Fish and Fisheries, in a letter to Congress in behalf of a small appropriation for fish propagation, gives some interesting facts regarding the scale on which the work of his commission has been conducted, and the future operations of that body. He states, in order to show the extent of operations, that the number of eggs of the California salmon alone, collected during the season of 1875 at the United States establishment on the Upper Sacramento river, amounted to about 11,000,000, making a bulk of 80 bushels, and weighing, with their packing, nearly 10 tons. The work of propagation has been successfully carried on in the Potomac river, in which from 6,000,000 to 10,000,000 pounds of shad and herring are now taken during the spring months alone. There is no reason, says Professor Baird, why any stream in the United States, having direct communication with the Gulf of Mexico or either ocean, may not be made to abound to an equal degree with these and other fishes.

A portion of this year's appropriation is to be devoted to the introduction of the European carp, a species eminently calculated for the warmer waters of the country, especially the mill ponds and sluggish rivers and ditches of the South. This fish often reaches a weight of six or seven and sometimes as high as eight pounds. Its length varies from six inches to two and a half feet. The upper portion of the body is a golden olive brown, and the abdomen is a whitish yellow. Its flesh is excellent eating; and as game the fish is but little inferior to the trout. It inhabits the fresh water lakes and streams of Central and Southern Europe, whence it has been spread by man over the northern portion. It prefers quiet waters with soft and muddy bottoms, and spawns in May or June, according to locality. The food consists of larvae of aquatic insects, worms and soft plants, though the fish will eat almost any vegetable food in artificial ponds.

The carp is probably the most canning of all fishes, although it can be easily tamed. It seems to learn the danger of hooks and baits, after a few of its fellows have been captured. Even the net, which is so effective with most fish, is often useless against the ready wiles of the carp, which will sometimes bary itself in the mud as the ground line approaches, so as to allow the net to pass over it; or if the ground be too hard for such a maneuver, it will shoot boldly from the bottom, leap over the upper edge of the net, and so escape into the water beyond. The fish has also the peculiarity of living to a great age, and it is said that carp exist in French ponds over a century old. It is tenacious of life, even when food fails and when removed from the water, and if carefully packed in wet moss so as to allow a free circulation of air, it will survive for weeks. Professor Baird anticipates no difficulty in domesticating this valuable fish in American waters, since it can be multiplied at very little expense even in restricted ponds.

Geometrical Chemistry.

A writer in the *Scientific American* says: In France, our Centennial year has been honored by the discovery of a new metal, to which its Gallic discoverer, Da Bois Baudran, has given the name of gallium. But 1876 was destined to higher chemical honors at home, for it witnessed here not merely the discovery of a new element, but the revelation of a new theory of chemistry, and the evolution of a new code of laws for its working. If the expectations of their author, Prof. Henry Wurtz, shall be justified, a grand revolution in theoretical chemistry is at hand, in comparison with which that of Laurent and Gerhardt was insignificant. One thing is certain: chemistry is still but a collection of generalizations. We have no theory of chemistry, as Dr. Crum Brown recently said, although we are struggling towards it. Here Prof. Wurtz comes to the rescue, offering us a theory which promises to explain many facts heretofore imperfectly understood, to correct our so-called rational formulas, to upset our theory of types and to open new avenues of research.

Prof. Wurtz begins by demonstrating mathematically the relative diameters of molecules in solids and liquids. Hitherto molecules have always been compared in a gaseous state, but he proposes to compare them as liquids or solids, and, as far as possible, at the temperature at which ice begins to melt, or just below 32 deg. Fah. His first remarkable discovery was that the relative volumes of various simple substances, in a solid or liquid state, whether

elements or compound radicals, as found by dividing their equivalents or atomic weights, as we are wont to call them (multiplied by 1,000 to avoid fractions), by their specific gravities, were perfect cubes of whole numbers.

Now it is well known that solid, whether cubes, spheres or polyhedra, are to each other as the cubes of their diameters; hence, thought our New Jersey chemist, the cube roots of these figures represent the diameters of our molecules.

For instance, the diamond has a specific gravity of about 3.555. The atomic weight of carbon is 12; if we divide 12,000 by 3.555 we have 3,375, which is the cube of 15; hence the molecule of carbon in the diamond has a diameter of 15.

The volume occupied by a molecule of carbon when in combination is, however, not constant, being usually 8,000, or 20th. The molecular volume of hydrogen is still less constant, but generally a perfect cube.

Oxygen alone retains a constant volume, viz., 5,184 (the cube of 17.3075), and hence Prof. Wurtz takes this as his standard for all other values.

In his memoir, published in a late number of the *American Chemist*, he adduces numerous examples to prove the truth of this discovery, showing that, whatever space an element occupies in a liquid or solid, at 32 deg. Fah., that space or volume can be represented by a perfect cube, whose root, of course, is the diameter of the space, be it cube or sphere. Such, in brief, is the distinguishing feature of the first part of the new discovery. Strangely enough, this law holds good for compound radicals as well as elements.

Limits of Perception in Regard to Musical Tones.

This subject is dealt with by Prof. Preyer, of Jena, in the first of a series of original papers on physiological subjects which are to be published under his editorial supervision. He has endeavored to fix the lowest and highest limits of pitch within which musical tones can be perceived, by means of experimental methods of greater precision than any that have been hitherto employed for the purpose. The minimum limit of the normal ear was found to lie between 16 and 24 single vibrations per second; the maximum limit reached 41,000; but many persons with average powers of hearing were found to be absolutely deaf to tones of 16,000, 12,000 and even fewer vibrations. The author then proceeds to inquire into the power of discriminating relative pitch and of appreciating musical intervals. In the last section of the paper he treats of silence, defining it as a state of uniform minimum excitation of the auditory nerve fibers, and joining issue with Fechner and others who deny its claim to be regarded as a positive form of sensation at all. Fechner distinguishes between the effect of absence of light upon the eye, and that of absence of sound upon the ear; black he regards as a sensation, silence as an absence of all sensation. Preyer points out, on the contrary, that the two cases are in every way analogous, and that the auditory organ never sinks, any more than the retina, below the zero of sensation. The pressure of the fluid contents of the labyrinth, and the flow of blood through the vessels, must give rise to the sensations of which we are unconscious only because of their uniformity, their constancy and their low degree of intensity. Silence, when the attention is concentrated on the sense of hearing, is found to vary in degree, just as the blackness of the visual field, when light is excluded from the eye, has been observed to vary. But the complete absence of sensation is obviously incapable of varying. Lastly, the parallel between the auditory sense and that of vision is borne out by a study of the entoptic sensations which may be produced artificially, and which are closely analogous to well known entoptic phenomena.

ELECTRIC LIGHTING.—Experiments in electric lighting have been continued at the Northern railway station, Paris. We hear that the Northern railway company will, if these trials are satisfactory, light the arrival depot by electricity. This building encloses a space of 300,000 cubic meters. For this purpose four electric lights will be used, rather more powerful than the one used in the luggage rooms and custom house, which is employed from five o'clock till midnight. At the trials of which we speak, a Gramme machine was being tested, giving a light equal to 100 jets of gas, consuming 150 liters an hour. At the factory of MM. Sautier and Lemmonier, experiments have lately been made with the photometer and dynamometer, the results of which show that this powerful machine gives a light equal to 1,850 Carcel burners. The equivalent consumption of oil would be 71 kilogrammes an hour; of gas, 194 cubic meters (equivalent to 650 kilogrammes of coal). The cost of the electric light is about one hundredth part of that of oil. — *Moniteur Industriel Belge*.

NEW APPLICATION OF INFUSORIAL EARTH.—Boettger publishes the observation that when an alcoholic solution of any of the coal-tar colors is mixed with a sufficient quantity of infusorial earth, water added, and the mixture filtered, the liquid will run off clear, while the earth retains all the pigment. Hitherto the compounds of alumina have been used for the production of the so-called lakes, and it is quite probable that the above noted behavior of this material, which is very cheap, may find important applications in the arts.

The Mining Share Market.

The business for the week has been rather dull; no new developments were heard of and a few dollars' difference was all indulged in in the bigger stocks. Small and so called wild cats found no grabe, and the people of California street show daily more and more that a square game of faro would be just as much appreciated by them as the most promising mining stock speculation.

The only excitement has been in Imperial, Alpha and Ophi, the latter not being much of a favorite until Friday. The advance in Imperial has been the principal topic of conversation during the week. The specimens of ore at the office taken from the winze sunk from the 2000-foot level are very fine, and are really finer than the rich ore taken from the Crown Point and Belcher. The large percentage of gold is one of its best features, it being over 60 per cent. The increased demand for Imperial did not have the effect of raising Alpha as much as it did some four weeks since. The north drift having been stopped where the winze is being sunk, it left the ground north in Alpha to be prospected through what is known as the Bullion drift. This drift is running diagonally across the ledge from the west wall and is in vein matter inside the black dike some 16 feet. It strikes the ledge from the west side. Reports were circulated during the week that the ledge had been passed through to the east wall, but it is not the case, and the reports no doubt were circulated for the purpose of buying stock. There is plenty of time within the next ten days for the drift running towards Exchequer and Bullion to demonstrate whether there is any ore in the 2000-foot level of Alpha or not.

There were the usual fractional variations in Yellow Jacket, Mexican, Exchequer, Savage, California, Consolidated Virginia, Best & Belcher, Gold & Curry and Union. Sierra Nevada, unlike Savage, continued to sink till near the end of the week under its oppressive assessment. Savage is a different proposition, and between this and election day some lively moves may be looked for if the signs of the times are not off their regular beat.

There was no session of the Pacific board on Wednesday afternoon on account of its being the first anniversary of their establishment.

MECHANICS' INSTITUTE FAIR.—An election of officers was held on Monday, 5th inst., with the following result: A. S. Hellidge, Henry L. Davis, George Spaulding, James Sperry, Asa R. Wells, James B. Stetson and James Drury. All the above were members of the old board. The installation of officers will take place at the rooms of the Institute, Saturday evening, June 10th. As soon as the Board is organized active measures will be taken for the furthering of the 11th industrial fair. A fine exhibit is anticipated.

NEPLAN & YOUNG.—We are pleased to notice that Neplan & Young, No. 18 and 20 Spear street, S. F., have recovered their footing from the confusion of the late fire, and are now ready for business with a fine display of steam mining pumps for draining mines, feeding boilers or elevating water. During a recent visit we saw the fine machinery which the firm sells all set up and ready for examination. It gives us pleasure to announce that the firm is again prepared for the patronage of the public.

HAND INJURED.—John Leffer, a workman at the new planing mill of the Consolidated Virginia mining company, had the fingers of one of his hands badly mangled and cut by being caught in the planer on Monday afternoon. His attending physician, Dr. Conn, found it necessary to amputate one of the fingers, but hopes to save the others. —*Gold Hill News.*

BLACK HILLS.—Just before closing we are in receipt of a report by the Department of the Interior, of Walter P. Jenney, E. M., on the mineral wealth, climate and rainfall and natural resources of the Black hills of Dakota. It will certainly be of interest and we will give notice of its contents next week.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SOFT-FOOT PATENTS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., June 8th, 1876.

FOR WEEK ENDING MAY 23d, 1876.

LIFE BOATS.—James F. Cosgro, Santa Clara, Cal.

RAILWAY CARRIAGES.—Emanuel Blochman, S. F., Cal.

TRADEMARK.

BITTERA.—Winder & Shearer, S. F., Cal., (two cases.)

It has been customary in old communities to suspend pieces of stick sulphur around the necks of children as a protection against contagion in epidemics. A thorough washing with GLENN'S SULPHUR SOAP has been found a much better preventive. Sold every where.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

General News Items.

The Sultan of Turkey has been deposed and committed suicide. His ancestor has been appointed.

A STORM of lightning struck two tonks of oil near Oil City, containing 44,000 barrels of oil; damage, \$100,000.

The American citizens of Paris have commenced a subscription to raise funds for the celebration of the Centennial Fourth of July, and for placing a marble slab, with a commemorative inscription, on the tomb of Lafayette.

Telegraphic reports give each day stronger and more numerous evidences of a state of feeling on the part of various European governments very adverse to the idea that peace can be long maintained. Russia desires to absorb Asia. She has already swept over a large portion of its territory, one might say dived over it like water. Great Britain has already control and government over a majority of the Asiatic population, excluding China. As a natural result those two governments are jealous of each other. The continuance of the Turkish Empire is thought by Great Britain to be necessary to the safety of her imperial possessions in Asia. Russia has long desired to slice off portions of Turkey and annex them. She wants free access to the Mediterranean sea. Great Britain is determined that the Dardanelles shall continue closed against her men-of-war. And to still more complicate matters, the new Sultan is a bitter enemy of the Khedive. Thus, and in many other respects, the affairs of Europe, Asia and Africa are very much mixed and tangled, and it looks as if war must result.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

OUR MINES.—*Chronicle*, June 3: The Advance company is pushing its work, and the very satisfactory showing of the value of its property, coupled with the rich developments in the Exchequer mine, is stimulating others to new efforts, not only in the Monitor and Silver Mountain districts, but throughout the other mining districts in the county. The great drawback mining in this county has now been overcome by the discovery of the O'Hara, Mindeff and Fryer processes for reducing rebellious ore. [A little less enthusiasm on this point would not hurt our cotemporary any.—*Eds. Press*]

THE ADVANCE.—To-night this shaft will be down about 230 feet. It is going down at the rate of at least 10 feet a week, so it will soon reach the 300 level, where they anticipate striking a heavy body of good milling ore.

AMADOR.

MONTREAL PLACER CLAIM.—*Amador Ledger*, June 3: The main channel is said to be 200 feet wide. About 20 small carloads from the 400-ft drift have been washed, and yielded at the rate of \$1.50 per carload—a remunerative return. The entire length of the tunnel is in dirt that prospects well, and will pay to hydraulic.

MARONET MINE.—The work of taking out rock commenced on this mine early in the week, and the Lincoln mill is now running to half its capacity in crushing the same.

CALAVERAS.

MINING ITEMS.—*Calaveras Chronicle*, June 3: The new steam pump lately put in the San Bruno shaft, at Mosquito, broke Thursday. We don't know what part of the pump broke, but it was necessary to send to San Francisco for castings. Good rock has been recently struck in the mine. Work is steadily progressing at the Grasshopper-sinking shaft and running levels. Splendid ore has been struck north of the shaft. Garland's mill started up the latter part of this week. Rock from the Haddock mine is to be crushed first.

GWYN MINE.—*Calaveras Citizen*, May 27: Work here progresses favorably, the bullion product being \$1,500 per day. Staking has been recommenced in order to be ready to run another level as soon as this is worked out. The news from the mine is exceedingly cheering.

COLUSA.

QUICKSILVER.—*Colusa Sun*, June 3: The report of W. R. Aldersley, the superintendent of the Abbott mine, shows: Number of days' run, 28; amount of ore reduced, 386 tons; number of flasks, 171.

CONTRA COSTA.

THE OLAYTON QUICKSILVER MINE.—*Contra Costa Gazette*, June 3d: At Olayton, on Saturday last, we saw two flasks of quicksilver which had just been brought in from the mine, the result of hand pan washing from the debris about the furnace. There is every reason to believe that work upon this mine will soon be actively resumed and prosecuted.

INYO.

DEFIANCE MINE.—*Coso News*, May 27: There are now being extracted from the mine 40 to 45 tons of ore per day, without the aid of hoisting works. These works will be put in operation next Monday, when the developments in the mine will proceed more rapidly.

GABRIEL.—The vein has been struck at the bottom of the incline shaft, which is now down about 100 feet. The face of the drift at the point of the cross-cutting is in splendid ore which assays 300 tons per ton. There is no longer any doubt as to the continuity of the ledge, and its width is now shown by the cross-cut and evidences on the surface to be 70 feet.

UNION COIN.—*Inyo Independent*, May 27: Operations on Cerro Gordo hill seem settled down to about the steady going thing in the county. Both furnaces are under constant fire, producing an average of 100 bars per each, of a grade of bullion for the market. In that place, though the ore worked is almost entirely "soft," just as it comes in the mine. The new working shaft, which is being both sunk and raised from the main tunnel level, is open to the surface from a depth of 320 feet and is now being timbered. Machinery for the hoisting works is lying on the dumps, and the necessary staking therefor is under headway.

LEE DISTRICT.—Sixteen miles north of Darwin, and nearly midway between that point and Cerro Gordo, is situated Lee district, one of the new mining localities now attracting attention in the southern portion of our county. The Cacuna mine, the most extensively worked of any in the district, belongs to the Emigrant mining company, an incorporation having J. B. Fink, Greenman and J. M. Taylor as trustees, the former acting superintendent. The company's mine, consisting of the Cactus, Valentine, Center, Philadelphia,

Capitalist, Centennial and Mountain View, are nearly all situated upon the summit of a cactus pampa, dividing the northern end of Panamint valley from the slopes toward Big Lake, the altitude of which cannot be more than 5,500 feet above the sea. The country is chiefly waste—the ledge presenting all sorts of curious shapes, lying under the black scoria cinder-piles. The Cactus seems to be an irregular body of extremely rich chloride ore, of an average width of five and one-half feet. At the date of our inspection, some three weeks or so ago, the opening in this particular mine was not deeper than 15 feet, but of a length and breadth three or four times that. Some 250 tons of ore, the poorest of which would readily work \$300 per ton, was in the dump. Of this class we have an interesting specimen showing the purest born silver, flecked with bunches of free gold. The Valentine, which is evidently a continuation of the same and showing well for the permanency of both, is a nearly upright ledge, opened by shaft and incline to a depth of 60 feet, at the bottom of which some good ore is to be seen. The Center and Philadelphia matter. The company have nearly completed a steam five-stamp mill, situated at Zacaton springs, some six miles distant, which we confidently predict will produce more bullion to the stamp—for the first few months at least—than any other mill ever erected on the coast. The company employ 20 men; have never levied an assessment, the expenses so far having been mainly defrayed by subscription to San Francisco. There is no Emigrant stock on the boards, and we understand none for sale. The other mines of the district bear the same general character, among which is the M'zeppa, a ledge producing the richest character of free chlorides, belonging to Messrs Walsh, Jordan & Watson.

NEVADA.

EUREKA.—*Foothill Tidings*, June 3: Official reports from this mine of last Saturday are to the following effect: Our clean-up for the last four days' run of 20 stamps, 12 hours per day, 14,400 ounces of amalgam. There are changes in No. 3. The Boardley claim has improved a little, showing a small ledge and a little sulphurets. No change in Eureka proper.

The Fryer works are for the present closed to the public.

PLACER.

GREEN VALLEY MINING.—*Dutch Flat Forum*, June 1: The Hidden Hill claim, under the superintendency of George Upel, cleaned up four of their boxes last week, after three weeks' washing, the result being 10 pounds of coarse gold. They are busy at present cleaning up bedrock, and we expect to hear of still larger results in a few days. This is one of the most extensive hydraulic mines in that vicinity. The Boardley claim. There are five men employed in this claim drifting; they are averaging \$8 per day to the man. Harper, Gathorpe & Co. have suspended work for the present, owing to the hard nature of their ground. They are making arrangements for 1,000 feet of iron pipe, which will give them the required amount of pressure to work their ground to good advantage. The Norway & Co. claim. They have been washing in this mine for five months; as their water is becoming scarce, they are preparing to drift. This mine has paid a large dividend this season.

TUOLUMNE.

THE SOUTHERLY MINE.—*Union Democrat*, June 3: The clean-up for the month of May in the Southerly mine resulted in a showing of 1,200 ounces, aggregating in coin \$20,400. The pans and concentrators have not been cleaned, and about three tons of sulphurets yet remain to be worked. It is thought that the sulphurets will yield about \$50 per ton. This is a most encouraging showing, and will do much to revive the quartz mining interests of the county.

BIG CLEAN-UP IN THE SOUTHERLY MINE.—*Tuolumne Independent*, June 3: The run this month was about 15 tons of ore per day, yielding over 1,200 ounces—at \$17 per ounce, \$20,400 gold. This amount was taken from the batteries only; the dies and pans not being cleaned up, is not included. Neither does this include the sulphurets saved in Schofield's sulphurets concentrator. In 26 days 10 tons of sulphurets were saved, which the superintendent averaged, and will go \$350 per ton, making \$3,500 for the month; besides this, \$126 in gold amalgam, escaping from the battery, was caught in the first hopper of the concentrator, which had it not been for the splendid machine, would have gone into the tailing race.

THE FORD LODE.—The Ford lode, on Bald mountain, formerly owned by Gorham & Wilson, has been sold to San Francisco capitalists for \$3,100. The new company propose to put on a large hydraulic and wash the entire mountain down. The old Ford mine has yielded hundreds of thousands of dollars, and there is no good reason why it should not do so again. The last work paid \$10 per day in the pan.

Arizona.

LOCAL MINING NEWS.—*Arizona Citizen*, May 20: Our letter from the Glob's district, written from Rambozcamp on May 1st, says: Nothing particularly new has occurred since our last report. The prospecting and more solid work in the way of developing leads already located, seem to be the order of the day. The Rescue shaft is progressing finely and looking better than ever. The Pinalia now down 95 feet, and a contract has been made during the past week for 50 feet more.

This mine has carried a very rich vein of ore from the surface. The Emigrant company will soon be at work with their stamms, which are nearly finished, and they have enough ore already exposed and only their dump to keep them busy a long time. The Meteor company's shaft measured 90 feet last Saturday, and the ore vein constantly widening and looking remarkably well. The Alice company have struck coarse gold in their shaft and are driving business harder than ever. The Richmond company have not done much lately; they are waiting for machinery and tools, which the owners have now gone to San Francisco to purchase. The Sherman is looking as well as ever and the owners are now sinking the third shaft.

PROB MINE.—*Arizona Miner*, May 26: The Agna Fria smelter has run through six tons of second class ore from the Prob mine, and on Saturday they brought in 1,718 ounces of refined silver bullion as a result.

Colorado.

FRYER PROCESS.—*Boulder News*, June 2: A representative of the Fryer process company is on the way to Colorado to introduce the process here. We are told that Mr. Charles E. Sherman, formerly of this town, is studying the process in California, and intends to introduce it here, if it proves an unqualified success.

GRANT COUNTY.—*Colorado Springs Gazette*, May 27: The mines of this county are being more extensively worked than ever before and with greater profit. In a short time every available mill will be in full operation, and some have been enlarged to meet the demand upon them. Upwards of 800 stamps will be employed through the summer. The year thus far has indicated a gold yield of \$2,500,000 for the county in 1876.

PAY ROCK.—*Colorado Miner*, May 27: This immense true fissure vein, situated on Sherman mountain, is undergoing active development under the efficient management of Mr. Thomas Ellis. From the level of the Silver Lake mine, a ledge of ore has been traced and sunk, from the bottom of which a cross-cut has been run north and south a distance of near 100 feet without finding either wall. Ore of good quality and quantity is to be found in all its different workings.

Idaho.

GOLDEN ORARIOT.—*Idaho Avalanche*, June 3: Work is progressing favorably in this mine and continued hope exists as to the prospective propitious results. Over 1,000 tons of ore are now lying at the mine and

the work of hauling it to the mill for crushing will commence in a few days. The roads are being put in shape for hauling and it is expected that the Golden Orariot mill will commence crushing rock next week. J. O. Hill has "struck it rich" in his Golden Age claim below Bonville. He had some of the rock assayed recently and it showed up \$650 to the ton, and according to all accounts there is a abundance of it.

NEW PLACER DIGGINGS.—*Idaho Statesman*, May 30: Placer diggings which are thought to be quite extensive have been discovered on Snake creek in Alturas county. The diggings as far as prospected pay from \$5 to \$7 per hand.

Montana.

A RICO VEIN.—*Helena Independent*, May 25: The recently discovered Nelly Grant lode, in Yankton district, near the head of Lump gulch, about fifteen miles from town, is turning out a magnificent bonanza. An experienced miner examined the lode yesterday and pronounces it among the finest in the Territory. About fifty tons of ore are on the dump. Unfortunately work on it has been stopped in consequence of litigation, and it may be some time before it is resumed. The width of the ore in the vein is said to be eight feet—good gleba.

TWO COW CREEK NUGGETS.—Yesterday and the day previous something over four thousand dollars in gold dust was purchased by the banks, being pretty equally divided between Messrs. Horn-bell & Bro. and the First National. The dust came mainly from Indian and Crow creeks and Last Chance gulch. From Crow creek were two large nuggets of a very fine quality of gold.

Utah.

UTAH MINES.—*Salt Lake Tribune*, June 2: The cars, dumps and emelters at West Jordan and Sandy are crowded with ore. The Grizzly mine is shipping nine thousand sacks of ore daily.

Nevada.

EUREKA DISTRICT.

HADLINO ORE.—*Eureka Sentinel*, May 30: Trains were started yesterday on the Eureka Consolidated railroad, for the hauling of ore from the mines to the furnaces. We understand the smelting works will be started up by the first of the month.

SPANISH BELT DISTRICT.

THE COUNTY INMATE.—*Eureka Sentinel*, May 30: A correspondent from Spanish Belt district writes: I am more satisfied than ever that we have a large body of ore in the present level, but the capping shows we are only on the top of the ledge. We have started a winze at the end of the north drift, the ore in which improves in width and richness as we go deeper. We have also started stoping on the hanging wall, at the end of the north drift, and, contrary to our expectations, we are getting out a large amount of rich ore.

WHITE PINE DISTRICT.

GOOD MILLING.—*White Pine News*, June 3: The Eberhardt mill started up on the 6th of May, and up to the 1st of June had only lost 17 minutes in stoppages. During that time it averaged 52½ tons daily through No. 50 screens. Perley Rowell says he would like to hear from any 30-stamp mill that has done more work.

PROMISING MINES.—A correspondent of the *New York Engineering and Mining Journal*, writing from San Francisco, has the following to say of one of the White Pine mining districts: The mine of Ward district, 65 miles northeast of White Pine, Nevada, an attracting considerable attention. The Paymaster lode has been opened to the depth of 160 feet, and shows 10 to 12 feet of good pay ore. All the working expenses have been met during the past year by shipping selected ore to this city, a distance of 900 miles by rail and 100 by wagon. There are large amounts of low grade ore in the mine, and the advent of a regular customer, the Ward district mines are sure to be well known all over the land.

BULLION.—The Eberhardt company, at White Pine, have 40 large bars of bullion on hand.

RAYMOND & ELIX.—No new work to report on this mine. The prospect work on the 8th, 9th, 10th and 11th levels continues to be pushed with good success. The extraction of ore continues at the rate of 200 tons averaging from 70 to 75 tons daily. The company mill at Bullionville is now running to its full capacity, 30 stamps, an account of an accumulation of ore. The Nevada Central trains are kept running steadily for the purpose of supplying the mill. No change in the stroke of the pump at the mine, it continuing to work with regularity. The first-class ore in this mine has general appearance of the mine continues favorable.

MEADOW VALLEY.—The machinery for the hoisting works of this mine is arriving very fast, and is being shipped from Eureka by fast teams as soon as the cars land it there. The tinning of the roof is nearly completed, the building presenting a very imposing appearance. The miners continue busily at work on the 1200-ft level with fair success. The regular employees are busy sinking a winze and doing prospect work.

ALPS.—Continue extracting daily 15 tons of ore from the mine, which assays and averages in working about the same. Work on the various levels continues as usual without any variation. The white quartz vein, containing free gold, continues to yield well; some parts of this ore are placed with a gangue of iron mineral, by which the full value of both grades of mineral are enabled to be extracted. The general appearance of the mine continues to look well.

ALPS MILL.—This mill for the past week has been running altogether on ore from the Alps mine and from Toquerville. Ten stamps are kept going for ore from the Alps mine and five for the Toquerville mine. The ore from Toquerville has generally worked well. Two lots arrived yesterday morning at the mill from that town, belonging to Ferris and Cochran; the battery was immediately started to work on them.

ANTILLAS.—Sinking on the main shaft of this mine progressed very well during the past week; the ground is so hard that the contractors made a prospecting shaft during the week. The work is being pushed rapidly. Considerable change has taken place in the formation, and prospects are fair.

PROB.—The work of sinking on the main shaft below 1000-ft level is progressing rapidly, the depth having been extended 10 feet during the week. The level from the 1000-ft station is being pushed forward rapidly in hope that a good body of ore may be struck at that depth, of which there is every indication. T. R. Butler, the superintendent of this mine, arrived from San Francisco yesterday.

AMERICAN FLAG.—Prospecting in the upper levels is going on with the usual force of men. These levels have a very encouraging look, presenting a prospect of a very fine body of ore in a short time. The contractors have not commenced yet to sink the 100 feet on the main shaft. They start to work on the 1st of June.

WASHOE DISTRICT.

GOUTIN & CURRY.—*Gold Hill News*, June 1: The new carpenter shop is finished, and the erection of the new pumping machinery is being pressed ahead with great energy. The repairs to the shaft are making steady progress. A new air machine for ventilating the mine is about being erected at the mouth of the old lower tunnel. The machine, instead of drawing air into the mine, is intended to draw the hot air, by means of suction, out of the mine, and thereby create a strong, healthy current of air from one portion of the mine to another. Experts in such matters look upon the new invention as a great improvement on the old process of ventilation.

BLOCKION.—The northeast drift on the 2000-ft level of the Imperial shaft is steadily advancing, the face in ledge material. It cannot be long now before the main ledge will be reached, although the drift will have some distance yet to run to reach the ore vein encountered in the north drift of the Imperial mine. The up-

raise from the 1700-ft level is making good progress; there is a slight seepage of water in the face of the raise.

YELLOW JACKET.—Sinking the north winze on the 1600-ft level is making excellent progress. It is now down 38 feet. Sinking the east winze below the level of cross-cut No. 3, on the same level, is going steadily forward, the bottom still in porphyry and quartz, mixed with streaks and spots of ore. It is now down 41 feet. East cross cut No. 2, on the 1910-ft level, is steadily advancing toward the ore vein. Cross-cut No. 1, from the bottom of the south winze on the same level, is also being advanced steadily.

SURETUNNEL.—Very good progress has been made since the last report. The enlargement of the main tunnel to regulation size is completed, allowing the small locomotives procured some time ago to be used to excellent advantage. Total length of tunnel, 13,311 feet.

BALE & NORCROSS.—The work on the pumping machinery at the surface is steadily advancing, every place where there is room for a workman being filled, and the whole being pressed toward completion with all the force possible. While the surface work is being done, enlarged bob and tank pits are being made at the proper intervals in the shaft, and the old pump columns are being hoisted to the surface ready to put the new ones in their place at the very earliest day possible.

NORTH CARSON.—Good progress is being made laying the pipes to convey the requisite supply of water from the flume of the Virginia and Gold Hill water company, and as soon as that is got through, which will be in about a week, the new hoisting works will be started up in good style. Meanwhile work in the mine is resumed and a new working shaft has already been put down to the depth of nearly 100 feet.

BELCHER.—Daily yield, 440 tons of ore. There are no changes to report of any of the ore-producing levels, nor can there be much until the new pumping machinery is completed and the water drained from the 1600-ft level.

LADY WASHINGTON.—Shaft continues making excellent progress downward, and the vein matter constantly improves, showing more quartz and the regular white ore Comstock ledge material as further depth is attained.

MONUMENTAL.—The shaft is down 165 feet, the bottom in good blasting ground. The sinking is making good progress.

IMPERIAL.—The prospects of opening up a fine paying body of ore on the 900-ft level are looking better. The north winze on that level, of which we have heretofore made mention, is to-day down 40 feet, the full size, 10 feet in width and eight feet in height, in ore that gives average assays of \$200 to \$300 per ton. The north drift on this level is being steadily advanced to the northward to connect with the Alpha drift. This drift, in order to make the connection for air at the earliest moment, is bearing more to the left, having left the ore body to the right in its course. It will have but a short distance to go to reach the Yellow Jacket on the 1940-ft level.

JUSTICE.—Daily yield, 30 tons of ore, which is being crushed at the Sherman and Excelsior mills. The ore stops on the 600-ft level and the opening up of the 40-ft level are all showing splendidly and promise a large yield of good ore. The north drift on the 800-ft level has penetrated a fine body of white, lively quartz of a very encouraging character. The north drift on the 1000-ft level a few days since tapped a strong flow of water, which has checked work in that quarter until it is drained.

CONSOLIDATED VIRGINIA.—Daily yield, 550 tons of ore, keeping the mills all running up to their full working capacity. The reports to the 1500-ft station, and the shaft below that point are completed. The east drift on the 1600-ft level running to connect with the drift from the C & C shaft is making steady progress. The drift running west from the 1500-ft station of the C & C shaft during the past week has been advanced 52 feet or seven and a half per day, a rate of speed that has hardly been excelled on the line of the Comstock. The north drift on the 1700-ft level is in a distance of 305 feet, running east of and parallel with the ore vein. The heat in this drift is so intense that but very slow progress is made.

OPHIR.—Daily yield, 180 tons of ore. There are no particular changes to note of the ore breasts or stops on either the 1500 or 1600-ft levels. The mine is showing well at all points. The north drift on the 1600-ft level is steadily advancing toward the ore vein. Sinking the main incline below the 1600-ft level is being carried forward at a very rapid rate of speed. The incline and upraise have something less than 100 feet to run to connect with each other, and when finished will place the shaft in the finest possible working condition down to the 1700-ft level.

CONDOR.—Daily yield, 350 tons of ore, keeping the mills running up to their full crushing capacities. The ore breasts are still showing as richly as ever, and the mine is opening up splendidly at all points. Air connections have now been made with the Ophir mine on the 1300, 1400, 1500 and 1600-ft levels, which, taken in connection with the ventilation afforded by the Consolidated Virginia on the south, gives the best circulation of air that it is possible to obtain. The hullion production for the month of May will probably not fall much short of \$1,750,000.

ALABAMA.—This mine comprises the northern portion of the Lady Bryan ledge, that mine having been recently divided into three claims, to be known as the Lady Bryan, Alabama and Tahoe. The company have just commenced work in good earnest on a fine three-compartment shaft, situated east of their ledge, and distant about 200 feet from the north and east of the Lady Bryan shaft. The prospects of this mine are excellent, as the ledge has already been followed to the south line by the north drift on the 380-ft level of the Lady Bryan.

JULIA.—The main west drift on the 1600-ft level has passed through the belt of hard rock recently encountered, and the face is now in much softer ground. The south drift on the same level is still in ledge material of a splendid character. On the 1300-ft level the main southwest drift is going slowly forward, the heat created by the boiling water being so intense as to considerably impede the rate of speed. The flow of water is gradually decreasing.

SILVER HILL.—Sinking the main incline is making fine progress, notwithstanding the rock is somewhat hard. The flow of water remains much the same as for some time past.

BROOKS.—The shaft has been sunk during the past week 15 feet, making a total depth of 113 feet. At that point what appeared to be the hanging wall of the ledge was cut, and a flow of water so strong encountered as to drive the miners from the shaft and stop all work. The present machinery is evidently inadequate to drain the water.

CHOLLAR.—Daily yield, 110 tons of ore, the assay value of which is \$32 per ton. Sinking the main incline is going ahead at the rate of 15 feet per week. No change in the east cross-cut on the 1350-ft level. Sinking the new combination shaft is making the usual fair rate of speed. The erection of the hoisting and pumping machinery is steadily advancing.

COSMOPOLITAN.—Face of main adit tunnel still in good ore, and pushing ahead toward the north line of the claim. The upraise above this level is fast nearing the surface, being 217 feet in height, and having only 29 feet further to go. A large amount of good pay ore has been developed by this winze.

OVERMAN.—Daily yield, 35 tons of ore. This ore is taken from the 900-ft level, which shows no change whatever of note. The station at the 1200-ft level of the shaft has been completed and a drift started for the ledge at that point.

ROCK ISLAND.—The quartz in the face of the main west drift on the 800-ft level is still showing considerable improvement in both looks and quality. The north drift on that level is steadily advancing, the face also in quartz. No changes in any of the prospecting

drifts on the 650-ft level, except in the ongoing south, which is showing a fine character of quartz.

GLASGOW.—The north winze below the 300-ft level, now being sunk on the ore body recently discovered, has encountered a flow of water so strong as to completely obstruct the progress of the work. It is the intention to immediately resume the sinking of the Combination shaft of the Amazon and Glasgow, to open another level and drain the flow of water at that point.

TABOE.—A combination shaft has been started directly on the dividing line between the Taboe and Lady Bryan claims. Each company is to pay half the expenses and own an equal share in the shaft.

BEST & BELCHER.—There is nothing doing in the mine at present except the making of some repairs to the incline winze from the 1500 to the 1700-ft levels, and nothing more can be done until the repairs to the Gould & Curry shaft are completed and the new pumping machinery is in good working order.

PROSPECT.—The shaft is down 239 feet, the bottom in good sinking ground. The new steam pump was set at work during the first part of the week, and is handling the water in good style.

ALTA.—The erection of the new pumping and hoisting machinery is making rapid headway. The foundations are getting well under way, and much of the machinery is ready to place in position ready for use.

SUPERIOR.—The grading for the hoisting works is completed, the machinery arrived and in position, and in the course of a day or so steam will be turned on and utilized in the further development of the mine. Work in the shaft will be resumed forthwith.

MEXICAN.—The chamber for the winze on the west side of the north drift on the 1455-ft level is completed. The shaft is now being sunk in the face of the drift, which is now being steadily advanced to the northward, as heretofore following the wall of the ore vein.

TWIN PEAKS.—The fine ore development at the 75-ft level shows better and better as further sought into. The formation thus far shows one of the regular ore features of the Comstock, and of the white ledge matter texture found at much greater depths.

WARD.—The shaft is now down 110 feet, the bottom in good sinking ground. The new steam machinery was started up yesterday and was found to work with the utmost perfection. Sinking the shaft can now be forwarded at a much more rapid rate of progress.

MINT.—Sinking the shaft is going steadily forward, the bottom still in soft ledge material. The prospect of the Mint are steadily growing more favorable and encouraging.

VIVIAN.—The ore stops are yielding the usual amount of good milling ore. The flow of water at the bottom of the main incline is steadily decreasing. As soon as the water is drained sinking the incline will be resumed for the purpose of opening a new level.

DAYTON.—Sinking the shaft is going rapidly forward. Driving the prospecting drifts on the 500-ft level, both north and south, is going forward as usual, without any valuable or important changes to report.

SAVAGE.—The pump tanks and bob pits in the shaft are completed, and the surface work on the foundations and machinery is being driven ahead with all the rapidity consistent with the perfection of the work.

UTAH.—Sinking the shaft is going ahead as usual without change of any kind whatever. Another pump lift has just been put in at the 650-ft level.

AMAZON.—The water tanks at the 300-ft level are flushed, and the pumps will commence to take the water from that point this afternoon. Sinking the shaft will be resumed at once, for the purpose of opening a new level.

UNION CONS.—The north drift on the 1300-ft level is steadily advancing, the face still in quartz and ledge material of favorable character.

KOSKUTZ.—The water has been drained, and now men are at work in every part of the mine, the same as before the flood. It will not take long now to reach the vein, when some lively developments may well be looked for.

NORTH COS. VIRGINIA.—Sinking the shaft is making excellent progress, the bottom still in soft ledge material. The flow of water is again increasing. Putting in the foundations for the new pumping machinery is going steadily forward.

NEVADA.—Sinking the main shaft is going ahead at a fair rate of progress. The prospecting drifts on the 1500, 1250 and 1000-ft levels are steadily advancing without any change worthy of note at any point.

ORIGINAL COMSTOCK.—The face of the tunnel has cut into good ore indications, and the bottom of the shaft is in softer rock than at last report. Something good in the way of paying ore is liable to be encountered very shortly.

NIAGARA POINT.—The south drift on the 1700-ft level is steadily advancing, without a change of any kind to record. The same may be said of the east cross-cut on the 1600-ft level.

LADY BRYAN.—The excavations and stonework for the foundations of the new machinery are going steadily forward, the work being pressed with all the vigor possible.

EMERALD AND AMERICAN FLAT.—Sinking the main incline is going ahead as usual.

EAST OVERMAN.—The quartz in the shaft shows improvement in proportion as depth is attained, giving a better showing for concentration into a large ore body, and a better assay.

PICTOR.—The station in the north drift being cut for the winze is nearly completed, and sinking the adit west winze will be commenced about day after tomorrow.

WEST BELCHER.—West drift is now in over 300 feet in fair working ground. The northwest is in 240 feet, still in low grade ore, which is improving some in assays.

PHIL SHERIDAN.—Sinking the shaft is making excellent headway, the bottom in soft, easy working ground, and no water whatever to interfere. It is now down 168 feet.

KNICKERBOCKER.—Excellent progress continues to be made sinking the shaft, the rock working favorably and water not impeding the work.

NEVADA.—Face of drift in softer and more favorable material. More streaks of quartz and low grade ore and less of the hard porphyry.

NIAGARA.—Sinking the main incline shaft is making good progress, the bottom still in soft ledge material. It is now down 313 feet.

CALEDONIA.—The work in this mine is still confined to sinking the main shaft, which is making grand progress. The flow of water is still strong.

SOUTH COS. VIRGINIA.—Some very good ore is being developed in the mine. All they have to do is to show pay more than the sinking of the shaft.

ORIGINAL GOLD HILL.—The retimbering of the shaft is completed at last, and sinking deeper for a new level is to be resumed forthwith.

BALTIMORE CONSOLIDATED.—The rock in the face of the drift continues getting a little softer, with other indications of approaching the ledge.

NIAGARA.—Sinking the shaft is being pushed ahead with the usual vigor. No change worthy of note.

NEW YORK CONSOLIDATED.—Work is progressing at all points with the usual vigor.

DANEY.—The work of putting in the water tanks at the 400-ft level is making steady progress.

LEVITAN.—The drift at the 600-ft level is now in 125 feet, with the face in hard rock.

MOORE.—Sinking the shaft is making good progress; otherwise there is no change.

SENATOR.—Sinking deeper is going forward at a lively rate, with excellent prospects.

COLUMBIA.—The enlargement of the shaft is rapidly approaching completion.

ROUGH & READY.—The adverse developments in the shaft still continue.

(Continued on Page 380.)

THE ENGINEER.

Straightening the Course of the Danube River.

The Danube River, through its subdivision into a large number of small branches, formerly produced, at the northeastern limit of the Austrian capital, an archipelago of islets. These were covered with beautiful groves, and to the people of Vienna, for over two centuries, the locality was a favored pleasure ground. Of late years, and especially since the woods have been cut down, the separate streams have dried or become marshes, and, in consequence, the salubrity of a portion of the city has been seriously impaired. Navigation also, always active on the river, has been, through the same cause, impeded, and despite the facilities offered to vessels by the canal which traverses the city, the necessity of engineering operations to improve and deepen the river has long been evident. The rapid extension of the northern faubourgs of the city has resulted in showing the need to be urgent, since severe and almost periodical inundations have caused large damage in the built up portions.

As early as 1810, the subject of the required improvements was agitated, but it was not until 1850 that any definite steps were taken toward beginning the enterprise. These, however, took the form of suggestions and projects but led to no practical results, and thus the matter lay in abeyance until, in 1862, a flood occurred, which submerged all the northern faubourgs, and carried great suffering into a population of over 100,000 souls. A new commission was then appointed to take prompt measures, and two years later this body seriously set to work to consider the large number of plans submitted to them. The following programme was finally decided upon:

1. To regulate the course of the Danube from the fields of Kuebelan, at the mouth of the canal, to Fischamend.
2. Extension of the project of straightening and improving above and below these limits.
3. Improvement of the section of the river, and of its accessory streams.
4. Defence of Vienna, by improved construction of new banks.
5. Deepening of the river-bed and feeding of the canal, so as to allow constant navigation.
6. Establishment of large loading quays and a winter harbor.
7. Construction of suitable accommodations for the reception of travelers, troops and their munitions of war.
8. Construction of docks, storehouses and basins, destined to transform Vienna into a great center of navigation, and to facilitate the transshipment of merchandise.
9. Establishment of quays over a distance of 4,700 meters, thus bringing the same and also the new river-bed nearer to the city.
10. Suitable arrangements for the construction of a central station for the railroads terminating at Vienna.
11. Construction of bridges and roads and of railroads on the Danube, with regard to the needs of navigation.

This vast programme was in principle accepted, but the mode of execution gave rise to long and vexed discussions, in which many engineers, Austrian and foreign, took part. Some advocated simply the improvement of the natural river-bed, while others maintained that an entirely new bed was necessary. The latter project was finally adopted, and the State, the province, and the city, the three parties interested in the rapid prosecution of the work, made arrangements to meet the estimated expense of 24,000,000 florins (about \$9,600,000).

A new commission was formed in March, 1869, charged with carrying out the details of the operation, and labor was at once begun, under the auspices of the French contractors, MM. Castor, Courreux and Hersent.

The new bed, 15 kilometers in length, commences at Nussdorf, above Vienna, and terminates below, at the village of Kaiser Eberdof.

It follows a slightly curved course, the convexity being turned toward the city, to which it is much nearer than was the natural bed. The entrance of the canal has been greatly improved, and provided with a lock which allows of its being closed during winter, and protects the city against the invasion of ice at the period of the breaking up of the same. The section of the new bed is divided into two parts; the minor bed, which ordinarily receives the greater portion of the water, is 285 meters long, and is from 3 to 3.5 meters in depth below mean level, or zero of the scale. The major bed, intended as a channel for surplus water, adds to the first a breadth of 515 meters, and its depth is two meters only below the mean level.

On the left bank there is an insubmersible dike elevated 6.3 meters above the mean level. On the right bank, a vast platform is made by the material dredged from the bed. This platform, completely sheltered from inundations, is designed to receive important constructions. The works to be executed were divided into the following:

	CUBIC METERS.
Earth excavations.....	6,557,000
Dredging.....	7,524,000
Masonry.....	207,000
Earthwork of slopes and foundations.....	448,800
Old foundations and piling removed.....	285,800
Fascine work.....	27,000

It was, besides, necessary to construct the lock at the head of the canal. A portion of the

excavation, about half, was executed by the shoveling into carts and barrows, but the balance was done by the excavator. This powerful machine was composed of a 20-horse power steam engine, which actuated a chain of hockets carried on a frame. The movement of the chain was such that the empty hockets descended from above the frame, while the full ones rose below. On reaching the emptying point, the vessels were discharged by automatic mechanism. The whole apparatus was mounted on a carriage which ran upon three rails; and a second steam engine, of four-horse power, served to move it from place to place. The excavated material, on leaving the hockets, fell into a conduit which led it to transport wagons running on a second and parallel railroad. The entire machinery, which had already been employed at the Suez canal excavation by the inventor, M. Courreux, gave at Vienna excellent results, both in point of economy and rapidity of work. The machinery employed during the entire operations included an immense amount of material. There were four excavators, nine dredgers, 18 locomotives, 397 wagons, 160 transport boats, besides steam cranes, stone breakers, towage vessels, etc., the mere care of which necessitated the construction of five huge workshops, besides extended barracks and hospitals for the large force of workmen.

A New Building Stone.

At a recent meeting of the English Society of Arts, Mr. W. Eassie, C. E., read a paper on the onyx deposits near the City of Mexico. Mr. Eassie said that some months ago he became acquainted with the product referred to, and examinations of it brought him to the conclusion that there had been unearthed for the use of succeeding generations a material which had never been eclipsed in point of natural magnificence. The people of ancient Rome, who were the predatory explorers of old, did not seem to have ever encountered so rich a material as the one before the meeting; and it would doubtless have remained practically unknown to Europe for another age had not the French expedition to Mexico, in support of the martyred Maximilian, taken in its wake the English railway contractor and his "navvy," and permitted its wholesale transport to England. Onyx was a chalcidonic variety of agate, arranged in flat horizontal planes of light, clear brown and opaque white. The deposits in question, however, were not formed in the cavities of trap rocks and the like, and was, therefore, neither onyx, chalcidony, agate, jasper, nor carnelian. It was rather an onyx-like marble, and really deserved a scientific name to itself. The applicability of this material, in following out the decorative faculty which imbedded man as he rose from the primitive conditions of life, would be seen at a glance. But its value as affording a new art material would be best understood by noticing the immense distances from which the ancients, during the early and more historical times, imported this very substance. Its application to the fine arts had not hitherto been very extended, owing to its recent introduction to Europe. Amongst the minor articles into which it had been manufactured, however, might be mentioned bowls, vases, stands of all kinds, handles of doors, etc., lamps and toilet ornaments. The future, however, of this new material would be seen, he verily believed, in the largest edifices of the country, in our mansions and in our clubs. After enumerating a few of the functions out of many in architecture which such a material as onyx might well perform, Mr. Eassie, in conclusion, to quote his own words, said that "the true position of this beautiful stranger amongst us is to lighten the duller charms of our own natural materials, and to relieve us from the abominable iteration of marble slabs here, there and everywhere—pillars of granite to the right of you, pillars to the left of you, and tiled walls and floors, upstairs and downstairs, and in my lady's chamber."

Moving Cleopatra's Needle.

Mr. Arthur Arnold has revived General Alexander's proposal to transport this famous obelisk to England and erect it on the Thames embankment, or some other suitable site, as an ornament to the metropolis. In a letter to the chief editor, Mr. Arnold expresses a high opinion of the beauty, condition and interest of the monolith. The hieroglyphics are still distinct, and although the edges of the carving and the angles of the monument itself are somewhat rounded, there is no important fracture discernible. The desirability of removing it must depend upon whether its value and interest are equal to the cost of removal; and as that is estimated at only £4,000 or £5,000, even if the authorities should hold back, the acquisition might be made by private subscription. Capt. Methuen, the senior captain and commodore of the Pacific and Oriental company, whom Mr. Arnold has consulted, is of opinion that the obelisk could be safely conveyed to London in an iron vessel not exceeding 400 tons builders' measurement, which he proposes should be constructed here, sent in pieces to Alexandria and put together in a space to be excavated below where the "needle" now lies, it having been first slung from girders, after which the short channel to the river could be easily cut, and the barge with its contents towed to England.—Iron.

GOOD HEALTH.

Mental Dyspepsia.

Concerning the real value of acquirement as a matter of discipline, authorities are not agreed. No doubt the mind may be strengthened by training, as the physical digestion and bodily health are improved by exercise. But with too many persons this discipline is the chip in the porridge that does little harm and no good. It is a serious question whether the men and women who load their minds with the juiceless roots and remnants of the dead languages and literature exclusively, are not in the condition of the fabled frog who swallowed the shot he could not digest, and which would not let him leap when he wanted to.

Brain exercise increases the development of the brain and stimulates its digestive power. But while this exercise is being taken, the physiological requisites of its healthy action must also be supplied. Some increment of knowledge must remain, or the student will become a mere literary pugilist, and not a producer.

Six weeks ago a girl of thirteen came to my clinic for relief from a distressing and intractable headache, which for some months had come on every morning and continued until two o'clock in the afternoon. The pain was severe, and her expression gave evidence of martyrdom. I said: "Do you go to school?" She answered "Yes." "For how long a time have you been to school?" "Three years." "How many studies have you?" "Eight." The case was one of mental dyspepsia, induced by over-feeding and cramming of the mind. And no wonder she was ill. If aight dishes were thrust upon the stomach, in season, and out of season, whether the appetite craved them or not, month after month, what would be the consequence?

This amount of mental pabulum was absorbed, but not assimilated. The poor girl had a load on her mind that was indigestible and alien to her faculties.

The brain revolted against such treatment, and her periodical headache was a sort of flagging the train, a signal of danger ahead. Of course the remedy was to take her from school and place her on a more sensible bill of fare. She was cured in two weeks.

In this matter of feeding the intellect, and of contributing to our mental growth, I know of no better rule than to obey the maxim which commands one to "stop while the appetite is good." If we read or study too much, or too many subjects or authors, the attention flags, the interest is gone, and then the mind does not seize upon thought factors with avidity. What clogs the appetite will clog the digestion. A loss of relish is a sign of depletion. There is a time to stop as well as a time to begin this brain work.—*Herald of Health.*

The Effect of Worrying.

Worry is defined in our dictionaries as a state of undue solicitude, anxiety, trouble. Shakespeare says that worry is

"A hell-bound that doth hunt us all to death;
A dog that hath his teeth before his eyes
To worry lambs and lap their gentle blood."

Shakespeare's picture is graphic, and one almost sees the monster before him. He personifies and makes it a creature visible to our senses, and all we have to do to escape his clutches is to run away or take our tomahawk to him. But, notwithstanding Shakespeare's graphic poetical statement, worry is not a creature at all, but simply an abnormal action of the mind to which we commonly attach very little importance; and yet which, if persisted in for any length of time, possesses elements of danger that will produce disastrous effects on the health and happiness of the individual. Worry is not a cheap and easy form of mental action, but an expensive one. The mind does not run smoothly, but with friction, heating the nervous machinery and destroying its substance. Worry is a nervous strain, a load of care and anxiety, which is too much. It comes on in times of mental weakness, when the person is tired, worn out, exhausted. Worry is more dangerous than overeating. Yea, it may be even more dangerous than drinking, bad as that is. It breaks down the body and mind. Worry is also useless. It is foolish. It is wrong. And yet most people will do it. Worry is a symptom of mental un-soundness. It does itself. The will cannot control it. It will not stop when ordered. It keeps on day and night often. It prevents sleep. It destroys appetite. It spoils digestion. It takes laughing away, and puts sighing in its place. The man always in a worry never sits down to the table with a heart full of thanksgiving. He never laughs or tells a funny story. His face is long. His heart is sad. His head is hot, and his feet and hands cold. He is not healthy. A perfectly healthy person never worries. He must begin to break down first. The nervous must first begin to tremble. Then worrying comes easy.

In these times, when the business of the country is depressed, there is far too much worrying. It don't do any good; but it does do much harm.—*M. L. Holbrook.*

DIER.—Say the vegetarians, 100 acres of good land will support a greater amount of human life, if planted to wheat, corn or potatoes, or products directly consumed by man, than if laid out in pasture or planted with vegetables designed to feed cattle. This may be true, but

all land is not cultivable to such crops as man feeds on, there being much land unfit for tillage that may be good pasture. Under the vegetarian regime, such land would furnish nothing directly for the food of man: so of forest and moor—game would cease. Vegetarians reject the products of the sea: milk, butter, cheese, beef, pork, mutton, poultry, fish, etc., are all rejected by the strict vegetarian. A mixed diet utilizes the products of the sea, the moor, the forest and grazing lands, as well as the products of tillage land.

Is Medicine a Science?

It is a nice question, in many cases, which has done the more hurt, the disease or the remedy; whether, for instance, the child's health suffer more from the intestinal parasites which vex him or from the destructive purgatives employed as anthelmintics; whether the cancer or the knife produces death more speedily; whether calomel or quinine be not utterly much such friends to the sick man as *Le Fontaine's* good-natured bear was to the gardener, whose mouth he crushed while trying to brush the flies off as he slept. It is an equally nice question to determine whether there ever really does occur a critical period in any disease, when the direct action of actual medicine, *per se*, can turn back the wavering life from the jaws of death to the flowery meads of re-established health; or, granting the possibility of such a rare occurrence, do we not run too great a risk, as a rule, to be able to profit by it? These are nice questions, as I have called them; nor does the present condition of medicine entitle us to expect to see them answered. For these reasons, among many others, medicine cannot be called a science.

It must not be supposed, however, that the doctor's office is to become a sinecure because his drugs are voted rubbish and his methods false. On the contrary, we shall need him quite as much and his advice will be more valuable to us than ever. He will not have it in his power to do harm, and consequently can give his undivided energies to the pursuit of good. It shall be his office to teach us the fallacy of physis. He shall present to our minds in all its horrid array the atrocious enormity of medicine as once it was practised, and so shall save many a poor sufferer amongst us from unconscious suicide. He shall be our perpetual beacon-light against the iron-bound, immitigable loadstone rock of quackery, where so many fair keels lie ntimely wrecked. In fine, he shall become to us the counterpart of that invaluable member of another profession, known as the chamber lawyer—a quiet man, of skill and experience, who abounds with all the wisdom and unction of pertinent counsel, and who never takes his client into court, where he bound to lose, no matter how his case is decided.—*Edward Spencer, in "The Atlantic" for May.*

USEFUL INFORMATION.

Fixing Pencil Lines and Colors on Drawings.

W. E. Debenham describes a method of fixing powder and other colors after they are applied: "I immerse the drawing in or flow over it a solution of freshly prepared moist gluten in alcohol, the alcohol to be at a strength of about 70 or 80 per cent., or a solution of gelatine or metagelatin or kindred substance (the word gelatine will be used hereafter to include kindred substances), in water, with as much alcohol added as the solution will bear without precipitating the gelatine. If the solution be hot, it will bear a large addition of alcohol. It is necessary that the solution be very alcoholic, or the colors may run, as they would in an ordinary aqueous solution. The gelatine coating may be rendered insoluble by treatment with tannin or chrome alum; the chrome alum is either added to the gelatine solution itself, or applied separately, and afterwards exposed to light.

"To prepare a photograph or drawing that color may adhere, I apply either of the alcoholic solutions already mentioned, or a solution of glycerine or sugar, or a mixture of any of these, and this preparative liquid should contain 50 per cent. or more of alcohol, in order that it may penetrate evenly. If the work can be colored before being mounted, as in the case of a photograph to be enameled, I apply the preparative liquid to the back of the paper. The alcohol makes it penetrate to the front, and the color is taken in a very even and fine manner.

"The fixing solutions are also applicable to water color, pencil and crayon drawings, and I prefer to employ gluten solution as an aqueous solution of gelatine, if desired, as an additional coat, or for the purpose of attaching it to the collodionized glass in enameling. The fixing solution itself may also be used for this latter purpose, and the coloring or touching is not to be disturbed. When it is required that the gluten solution should contain more gluten than the alcohol will take up, I evaporate rapidly, but not to precipitation, a portion of the solution, and mix with the remainder."

To whiten lace, iron it slightly, and sew it up in a linen bag; let the bag remain for 24 hours in pure olive oil. Then boil the bag in soap and water for 15 minutes, rinse in warm water, and then dip into water containing a slight proportion of starch. Take the lace from the bag and stretch it out to dry.

"Alloy" and "Amalgam."

Science often makes a wrong use of words. When we want to know the reason for a broad meaning that any word bears, we seek the root. Words in science are so often at variance with their derivation as to fail at first sight or hearing to convey a hint of their intended meaning.

When we get the derivation of a word we have its literal or restricted sense; from this we can ascertain to what degree the broad or popular meaning is justified. See how variously the word alloy is used.

Chemists use the word "alloy," to any mixture of metals, minus mercury; but, if mercury be one of the parts, then the result is an "amalgam."

In coinage, to alloy is to mix an inferior with a superior metal.

A recognized author on metallurgical science says: "The body formed by the union or combination of two or more metals with each other is termed an 'alloy' and if one of the constituent metals be mercury, the resulting substance is known as 'amalgam.'"

Webster—"Alloy, *v. t.* To mix one metal with another; to reduce or deteriorate by mixture;—*n.*, a baser metal mixed with a finer, or a mixture of metals; that which reduces or deteriorates.

The root: "Alloyer," French to "mix." O perhaps from the Latin "*aligo*," to join, to bind.

This science gives alloy a broader meaning than is given to it by the lexicographer, and one that we like better. Still, in its every use there is a more strict adherence to its literal meaning than we always find. Richard Grant White—proprietor of the English language—might be prevented from frequent convulsions were there no greater torsional subjections of derivation than making any mixture to mean only a mixture of an inferior metal with a superior.

In "alloy," we intend to abandon Webster and the coiners, and to accept the chemists and any mixture of metals that is minus mercury. In this, we accept the popular usage and are supported by Guizot: "When the meaning of a word, on the other hand, is determined by science, this determination, the work of one individual, or a small number of individuals, takes place under the influence of some particular fact which has struck upon their mind. Thus scientific definitions are, in general, much less accurate, much less true at bottom, than the popular meanings of the terms."—*American Manufacturer.*

CHARCOAL FOR GUNPOWDER.—Dogwood (*Rhamnus frangula*), which is used for gunpowder charcoal, is supplied in bundles of long slender rods. The bundles are about six feet long, and should be thirty inches in girth at one foot from the thick end, and diminish about four inches in girth at the upper end. The wood must be perfectly free from bark, and clean. Great stress is always laid on the cleanness of the wood used for conversion into charcoal at Waltham abbey; any traces of bark adhering to it constitute an impurity, and would condemn a supply sent in by a contractor. The specifications imposed on contractors provide that the wood shall be cut in the spring of the year. If this has been done when the sap is rising, the bark is easily removed, and the wood is left perfectly clean; but wood cut later in the year, or in winter, is perfectly as good, only in this case the removal of the bark is a much more difficult matter. To separate it the wood must be boiled, or if that is impracticable, the whole of the bark must be shaved off with a knife or spokeshave. Both boiled and shaved have been used at Waltham abbey, but the great objection to both is that they do not keep so well when stacked as the spring-cut wood, which goes to decay much faster.

FLOWER POTS.—We learn from the *Hamburger Gartenzeitung* that the fabrication of flower pots from a mixture of cowdung and earth is now extensively practiced in Germany, 16,000 being used last year in one establishment. For forcing they are highly recommended, though they will not bear plunging in a hot-bed; and they are admirably adapted for nursery work, for plants raised in pots and afterwards turned out, in this case pot and all. Even standing dry, the roots of plants will penetrate the sides of the pot, and extract some nourishment from them. They are made by machinery, and one man can make from 700 to 900, or even 1,000, in 10 working hours. There are machines for two sizes, two inches by two (price \$2), and two and three-quarter inches broad by two and one quarter high (price \$2.50).

LIQUID GLUE.—One part phosphoric acid, specific gravity 1.120, diluted with two parts water, is nearly neutralized with ammonium carbonate, one part of water added, and then, in a porcelain vessel, sufficient glue dissolved in the liquid to obtain a sirupy consistence. It must be kept in well closed bottles. The addition of glycerine or sugar would cause the glue to gelatinize.

SMALL SEEDS IN A POUND.—The number of seeds of wheat in one pound is 10,500; the number of seeds in one pound of barley is 15,400; the number of seeds in one pound of oats, 20,000; the number of seeds in one pound of rye, 23,000; the number of seeds in one pound of buckwheat, 25,000; the number of seeds in one pound of red clover, 249,600; the number of seeds in one pound of white clover, 686,400.

FRAUDS IN SILKS.—The debasement of silks by foreign admixture, if we may infer from the comments of journals devoted to textile interests, has of late reached such a height as to promise shortly to rival that of a class of cotton goods which have added largely to the notoriety, if not to the fame, of one of the manufacturing centers of England. A writer to one of the French journals shows that the weighting of black silks—which began with the modest aim of making up for the loss sustained in ungumming—is now carried to the extent of 100, 200 and 300 per cent. This increase of weight is effected by treatment with salts of iron and astrinents, salts of tin and cyanides. The balk is augmented proportionately to this weight. The same writer points out very clearly the evils attending this excessive adulteration. The chemical and physical properties of the silk thus treated are materially modified. What is sold as silk is, in reality, a mere agglomeration of heterogeneous matters devoid of cohesion, held together temporarily by a small portion of silk. The strength and elasticity of the fiber are likewise reduced. From being in its natural state one of the most stable of substances, and but slightly combustible, in its adulterated state it burns like tinder if touched by a flame. It is likewise affirmed to be liable to undergo spontaneous decomposition, and to absorb gases with the evolution of heat which sometimes leads to actual combustion. The adulterated silk when burning scarcely gives off the characteristics odor of animal matter.

INDELIBLE INK.—Two-fifths of a pound of tartaric acid dissolved in 61 cubic inches of hot water; in one-half of the solution dissolve one-fifth pound oily aniline; add the other half, and then one-fifth pound chloride of potassium. Allow the solution to cool and subside until next day; filter from the bitartrate, and bring the liquid to the density of seven degs. B. Thicken sufficiently with gum arabic, and add to each cubic inch one-twenty-fifth of a pound of copper sulphate, dissolved in a little water. This ink may be at once used for printing muslin and other fabrics, upon which the black color will be perfectly developed by bleaching liquids. Chlorate of copper is also used for writing upon zinc signs and labels exposed to the weather.

SERIOUS ENGINEERING MISCALCULATION.—No blundering that has been heard of in the railroad world since some of the earliest English contracts for construction, approaches in magnitude, says the *Pall Mall Gazette*, the mistake that has been made about the cost of the St. Gothard tunnel and the lines connected with it. The company which has undertaken this great work, the completion of which was promised for 1880, started with a subscribed capital of 34,000,000 francs in shares, and 68,000,000 francs raised by debentures, together with an international subvention of 85,000,000 francs, of which Italy was to contribute more than half, while the German and Swiss governments were to be equally responsible for the remainder. Thus the whole estimated cost of the enterprise, 187,000,000 francs, was provided for, and the works were begun with a confident assurance of speedy progress. A few months ago, however, some doubts arose as to the efficiency of the direction and the soundness of the estimates. A new "director" was appointed, whose inquiries resulted in the conclusion that the execution of the plan in its integrity would involve an expenditure of nearly 300,000,000 francs. The Board of Administration will meet at Lucerne to consider the state of affairs; but it is difficult to see what course can be suggested for raising the new capital required.

ANTIMONY.—We take from the *Iron Age* the following note: "There are two antimony of note in England, Cookson's brand being the best one on this side, the other brand being that of Hall's. They rank about equal. These brands at all times command the top of the market here, and they furnish us about nine-tenths of the entire quantity we consume. Our consumption may be put down as amounting to 3,000 tons annually. Any supply above this quantity would be in excess, unless the consumption increased in proportion, for which there is no prospect at present. The ores of the United States are reduced to star metal, chiefly in Nevada, where there are several smelting works; those in other localities as yet amount to very little. As for the domestic article, it has not yet attained the perfection of the English antimony, hence a good deal of our ore is shipped to England, since we are as yet unable to extract the metal from it economically enough to make it pay, notwithstanding the duty which protects us."

A MONUMENT TO BESSEMER.—Mr. Jacob Reese, of Pittsburg, proposes that a monument be erected to Henry Bessemer, which shall be constructed as follows: "Firm in the foundations of the ages, let us build on Catalan lumps a mammoth base of charcoal metal and mark it Hogge—and on it place a cheaper cast of raw aol iron in memory of Dad Dudley and, higher still, a Darby coke iron block, capped with Roebuck's porous metal, and from thence upward to the heavens project a cone of a better, cheaper, purer metal, marked in spectroscopic lines of gold to Bessemer. And while we view this mighty work, from rugged base to shining apex, let us not forget the path they trod, the difficulties which they encountered, and the necessity of the intervening age for the pending process. And around this monument of glory let us pile with willing hands dephosphorized puddle balls in such design that all may read with pleasure the name of Henry Cort."

ADVERTISING RATES—1 week, 1 month, 3 months, 1 year.			
Per line.....	25	80	\$4.00
One-half inch.....	1.00	3.00	7.50
One inch.....	1.50	4.00	12.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions payable in advance—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

THE ORIGINAL ARTICLES in this paper are mostly in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, June 10, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Paul Process; The Bonanza on Bernal Heights; Notices of Recent Patents, 369. Some of the Mines of El Dorado County; How Valuable Mines Should be Recognized, Prospected and Worked; Gems and Precious Stones, 376. The Centennial at Philadelphia; A Simple Pumping Power, 377.

ILLUSTRATIONS.—Plan of Paul's Dry Process for Working Gold and Silver Ore, 369. Horse Power for Operating Pumps, 377.

MECHANICAL PROGRESS.—Locomotive for Working Steep Gradients; Telegraph Wires and Insulators; Mechanical Puddling; Keep off the Railway Tracks; Russian Manufacture, 371.

SCIENTIFIC PROGRESS.—The Work of the United States Fish Commission; Geometrical Chemistry; Limits of Perception in regard to Musical Tones; Electric Lighting; New Application of Infernal Earth, 371.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 372.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 373 and other pages.

MINING SUMMARY from various countries in California, Nevada, Arizona, Montana, Idaho, Colorado and Utah, 373-4.

THE ENGINEER.—Straightening the Course of the Danube River; A New Building Stone; Moving Cleopatra's Needle, 374.

GOOD HEALTH.—Mental Dystopia; The Effect of Worrying; Diet; Is Medicine a science? 375.

USEFUL INFORMATION.—Fixing Pencil Lines and Colors on Drawings; "Alloy" and "Amalgam"; Chemical for Gunpowder; Flower Pots; Liquid Glass; Small Seeds in a Pound; Frauds in Silks; Indelible Ink, 375.

MISCELLANEOUS ARTICLES.—The Trial of Agricultural Machinery at Stockton; Study of American Mine and Metallurgical Works by Foreign Engineers; An Ingenious Workman; Abolishing Telegraph poles; Washing with Hard Water; Patent Horse and Cattle Groomer; Bill to Restrict Chinese Emigration; Suez Canal; The American Society of Civil Engineers, 376. Serious Engineering Miscellany; Antimony; A Monument to Bessemer, 376.

NEW ADVERTISEMENTS.

Cook's Patent Automatic Boiler Feeder and Regulator, Pacific Iron Works, S. F.; Mariposa Land and Mining Company—Sale.

A NEW PHASE IN GOLD MINING.—Since the discovery of gold in taloo-slate a few months ago and the active development of a mine of that description in El Dorado county by the Old Hickory gold mining company, a great interest in that peculiar formation has been displayed by our miners, and we will therefore give a short description of the material and its constituents.

Taloo-slate, or the elaty formation of steatite, is of primary period and generally found in large ledges and deposits in the slate range. It is ordinarily called soapstone and consists of silica 62.6, magnesia 32.5, water 4.9. It is perfectly fire-proof and of the same class as asbestos, and considering that its hardness is only two, to seven, of quartz, we dare say that the stamping or rather grinding of it can be done very easily. The company now developing the first mine of that description on this coast have 22 feet of a ledge, the assays of which run from \$50 to \$200 per ton, and we are credibly informed that the ore, on account of its softness, will work by pan amalgamation with alkali, for \$2.00 per ton. The sulphurates contained in the ore assay \$329 per ton and constitute about five per cent. As the ledge is traceable for miles we may shortly look for interesting developments in that quarter.

NEW PUBLICATIONS.—Through courtesy of Messrs. Banoroff & Co. we are in receipt of the following new works:—"Bridge and Tunnel Centers," by John B. McMaster; Nostrand, publisher, New York. "Notes on the Treatment of Mercury in Northern California," by T. Egleston; Sherman & Co., publishers, Philadelphia.

Some of the Mines of El Dorado County.

[By our own Correspondent.—No. 2.]

Ten or 12 miles east of Placerville is Pleasant Valley. To say that it is appropriately named is a sufficient description of the village and the beauties of its surroundings.

There is an excellent public school under the charge of Mr. Geo. F. Mack; a mile above is the El Dorado door factory, owned by Messrs. Wilson Bros., of your city, where doors, sash and blinds of all kinds are manufactured in large quantity. The doors are clamped up by a steam power endless screw clamp, a late invention, I understand, of Mr. H. O. Hooper, of San Francisco. The doors are passed through a diagonal planer, giving one uniform surface to them within a few moments, and afterwards polished by means of Smith's patented elbow machine.

Last year the factory turned out 8,000 pairs of blinds, 24,000 pairs of sash and 40,000 doors, giving employment to about 60 men. About 1,700,000 feet of lumber was used, the chief supply being obtained from the

Baltic Mill,

Six miles above Sly Park, owned by Mr. Louis Lepetit, who cut last year over 2,000,000 feet, principally of sugar pine, and who intends this year to saw about half a million more. His mill gives employment, directly and indirectly, to 10 large teams and not less than 40 men. Mr. L. is now building a wooden track railway from his mill to Sly Park, a distance of six miles, at a cost of perhaps \$4,000 per mile, for the purpose of increasing the supply of lumber and lessening the expense of getting it out for the market.

In the upper portion of the county there is A Very Large Business Done

In the way of getting lumber, many mills running and employing a very considerable amount of labor. Mr. Cutler at Sly Park informs me that he cut last year at his mill about 850,000 feet.

Messrs J. & J. Blair, of Placerville, are perhaps doing the largest business in this line. They have three mills which can cut 50,000 feet per day. From Sly Park, a very beautiful little valley and fine summer resort, I crossed by a blind trail over lofty ridges and down into deep ravines, over several forks of the Cosumnes, about eight miles to Grizzly Flat. Let no stranger to the country attempt to thread that labyrinth. I should have been lost but for the kindness of a good Samaritan found on the way. This is the home of the rattlesnake; a nest of upwards of 70 was recently found here. I kept a sharp eye out for them, but saw none.

Some Quartz Veins.

Two miles north of Grizzly Flat a small quartz vein, varying from 4 inches to 14 inches in width, was visited; owned and worked by Mr. Adam Branthover for the past two years. There is a four stamp mill at the mine run by a burdy-gurdy wheel 750 feet pressure. The ledge is tapped by a 200-foot tunnel to the depth of 100 feet.

The ore has paid from \$10 to \$18 per ton, and would in all probability, (judging from the character of the rock and the manner in which it prospects by hand mortar and pans), have reached \$30 or \$40 per ton if all the proper appliances for saving the gold in the ore and sulphurates had been used.

Soon reached the works of the Eagle mill and mining company, situated within one mile of the Flat. The ledge is in a granite formation, under the superintendence of Mr. John Tregloan, an experienced miner, and well known in Storey county, Nevada.

Your correspondent was sorely disappointed to find that he was absent in San Francisco. He had expected to obtain from him much reliable information, as he was an acquaintance of years long ago numbered with the past. His faithful young foreman creditably furnished the necessary information.

The ledge will average from five to six feet in width. Main shaft 240 feet, tunnel 475 feet, running along the ledge at least 400 feet, reaching a depth from surface of 140 feet. Much good ore has been taken out of the mine in the past. It had lain idle several years, and operations were commenced again last December. The company are now running a prospecting tunnel, with the view of striking the chimneys found in the old tunnel, 100 feet deeper. In the meantime they are crushing rock from the upper tunnel at Mr. Morey's 5-stamp mill, which pays from \$8 to \$18 per ton. The company contemplate building a mill at an early day. The quartz looked well and the prospects for the company are very flattering.

Almost within sight of the Eagle, is the Mt. Pleasant quartz mine, owned by Mr. O. D. Lambard. It has been worked steadily for the last 18 months. The tunnel, 370 feet in length, intersects the vein, (which is not that point 11 feet in width), at a depth of 130 feet from the surface. The average width of ledge is six feet. Drifts have been run north and south 120 feet, and the ore pays from \$20 to \$40 per ton. The 10-stamp mill below the mine is kept pounding away by day and night, run by water burdy gurdy wheel, pressure 340 feet. Eighteen men are employed. Mr. Wm. Teague, the gentlemanly superintendent, to whom I am indebted for many of the facts in reference to this valuable mine, said that he had worked it for a period of six years, from 1868 to 1874, had sunk a shaft 400 feet, and during that time had done

much prospecting at a cost of about \$60,000. Rich ore has at last been struck, and the mine is yielding a good harvest in return for the time, labor and money previously spent. The sulphurates are worth \$400 per ton.

Free gold is plainly visible in much of the ore, without the aid of spectacles. It bids fair to prove one of the best paying mines in the State. May it long continue to pour forth its treasures!

Now, my dear reader, I am going to divulge a little secret, which is only intended for your ears. On my way, three miles from Grizzly Flat, near trail leading to Mandon, I quietly stole in upon Mr. Gabe Wernitz, a bachelor, I suspect, for he was making cakes. So, while he was busy, I slipped into my pocket a rich quartz specimen, found in the

Secret Lode,

Which he has been secretly working, and doing fully as well, if not a great deal better, than his neighbors imagine. The specimen I pocketed he gave me, which I forgot to state; but it was not from a pocket lode, but from one which has every appearance of being a true fissure vein, granites forming the east and hanging wall and slate the west. It is not large. Good things are often packed in small bundles. It varies from six inches to 20 inches in width. It has three paying chutes, works, by mill process, from \$15 to \$20 per ton, average assays from \$100 to \$150, and ought to pay at least from \$60 to \$100, if he only knew the secret of the Fryer, or some other good process of reducing his ores and sulphurates. It is opened by a tunnel, 225 feet on the lode. A further run of 100 feet will obtain a depth from surface of 225 feet, and will reach all the paying chimneys.

Between this point—Henry's Diggings and Mandon—is the Crystal mine, owned by S. S. Alexander, of Oakland. It is not worked at present, but operations will probably soon commence. Heard it highly spoken of by Mr. Bradley, who is interested in an extensive gravel claim at Henry's Diggings, which, by this way, will receive due notice, with other claims under the general heading of "Hydraulic Mining South of the American River." K.

How Valuable Mines should be Recognized, Prospected and Worked.

[For the Press by E. G. G.—No. 2.]

To recognize and prospect the three classes of mineral veins or deposits enumerated in our last, should be proceeded upon the following plan:

Fissure Veins.

An inclined shaft should be sunk with the ledge and on the hanging wall of it for at least 50 feet, so as to insure a correct view of the dip. If such dip is less than 45 degrees from the horizontal, it would be well to abandon the ledge; experience has shown that no fissure vein or paying lode has less than 45 degrees.

But if the investigation as to the dip is satisfactory, proceed to run some 20 feet horizontally either way from the shaft along the hanging wall of the ledge, thus enabling you to obtain the exact course of the ledge with reasonable certainty. Now cross through the ledge to the foot wall on both ends of your drifts, and repeat the operation, if satisfactory on one place on two or three different places of your claim and you can prove to yourself or any outsider or mining expert the value of your claim at a glance. You can then proceed to work in a systematic manner, as will be explained hereafter.

This is for fissure veins. If you have a smooth hanging wall and a rugged foot wall (the latter, though, may be smooth here and there) no matter what the bedrock consists of, you can count with a reasonable certainty on having a true fissure vein. Gold ledges are found in primary period formation; slate, syenite, gneiss, etc., and eliver in all older formations, but can hardly be looked for in limestone.

On Wedge-shaped Mineral Deposits,

As described in our last, you will by going down on the hanging wall find the same rugged and varying vertically as well as horizontally, while the foot wall is in most cases as the hanging wall in fissure veins. A reasonable amount of prospecting should be done on both walls and at some depth before you draw your conclusions. Deposits of this sort may be valuable, especially if gold bearing, but can hardly be recommended for a legitimate mining enterprise. In mountains which are bare and allow their whole formation to be recognized, these veins are found on the side, and you can readily infer there is a true ledge further up which may be prospected for accordingly. But on formations which have been much subject to the water or glacial period, the caps of such mountains might have been displaced and you are apt to find the mentioned deposits on what is apparently the top of the hill. At any rate, ledges of that sort are never a great distance from a fissure vein.

Now to the third class, the

Mineral Slides.

They are caps of ledges carried away and deposited elsewhere, and can be easily recognized as such by their contents. The ore in

them is found to consist of sharp angled shattered fragments, cased, no doubt, by the sliding motion which has kept the whole in place but shattered its contents. Such caps are generally of no value but have sometimes for their extreme richness been the cause of serious disappointments.

(To be Continued.)

Gems and Precious Stones.

[Written for the Press by HENRY G. HANES.]

(Continued from last Week.)

D. Spinel—Spinel Ruby, Almandine Ruby, Balas Ruby, Rubicelle, Pleonast.

When pure the spinel has the following composition: $MgO + Al_2O_3$; magnesia 28, alumina 72, = 100. But it frequently is found with part of this magnesia replaced by protoxide of iron, lime or manganese. The alumina on the other hand gives way to the sesquioxide of iron in part, so taken on the whole the composition is somewhat mixed and doubtful; but in treating this mineral as a gem we have only to consider the purer forms.

The spinel ruby is deep red or scarlet; the balas ruby is rose red; the rubicelle is yellowish or orange red; the almandine is violet, while the pleonast is black.

Blue, yellow and green varieties are of rare occurrence. The blue is called sapphire and the green chlorospinel.

This mineral is often confounded with the garnet, which is erroneous, for all varieties of garnet contain silica, which the true spinel does not.

Spinel scratches quartz, but is scratched by the sapphire. Its specific gravity is from 3.5 to 4.1. The red variety has a specific gravity of 3.523, while the black is 3.575. Luster vitreous to splendid, from opaque to transparent. B. E. the spinel remains infusible if no fluxes are added. The red variety changes to brown or even black, on cooling changes to green and then returns to the original color after passing through several tints. Borax dissolves it slowly; so does microcosmic salt more readily, taking from the mineral a reddish hue when hot, and cooling to a faint chrome green color. Soluble, but with difficulty, in highly concentrated sulphuric acid; wholly decomposed by fusion with bisulphate of potash. Swells up with soda but does not fuse.

The spinel crystallizes in the isometric system, the crystals being octahedrons and their modifications. Although it has been shown that the spinel is found of many colors, yet the streak or powder is always white. Its fracture is conchoidal.

The name "carbunculus" was applied to this gem by the ancients, and also "spinella carbunculus." It is not uncommon at the present day to hear red garnets called "carbuncles," especially if they are large and are out cabochon.

Spinel is sometimes found imbedded in granular limestone and associated with serpentine and gneiss. The purest stones come from Ceylon and Siam, where they are generally found as rolled pebbles. It has been found in a similar form in Arizona. It is not uncommon to find it in cavities of lava from some volcanoes.

In the United States it is also found near Amity, N. Y., and Aadover, N. J., but never of a quality to be used as gems.

The blue spinel (sapphire) comes from Sweden. The pleonast or black spinel is found in Ceylon, Bohemia, Tyrol and at Andernach on the Rhine. Small crystals of this variety, of extraordinary luster, are found in old lava on Mount Somma.

The spinel does not become electrical either by friction or heat, nor does it doubly refract light.

There is said to be a tradition in Persia that the mines producing this gem were not known until after a terrible earthquake, which split a mountain from summit to base, and that first they were mistaken for the true ruby.

There is no reason why the spinel should ever be mistaken for ruby. The test of hardness alone is sufficient to distinguish them; holding the stones for a moment on an emery wheel will at once show them to differ. The ruby can scarcely be scratched, while the spinel yields immediately. The difference in specific gravity is also a test easily applied if the stone is unset.

It is impossible to set a value on the spinel; the price fluctuates with the fashion, or, like other goods, with the supply and demand. As an instance, I find it stated that a stone weighing 40 carats of good quality sold in England in 1856 for £400; was sold afterwards at auction for £80, after which it was again sold for £240. The present price of the best quality of spinels may be taken at from \$2.50 to \$40 per carat.

The spinel has been made artificially by strongly heating alumina, magnesia and boracic acid. Another method is to fuse the fluoride of magnesia and aluminum with boracic acid; and still another, to act on magnesium with vapor of chloride of aluminum.

O. F. LIBRARY ASSOCIATION.—We have received the 21st annual report of the S. F. Odd Fellows' library association for the years '75-6. It contains the annual report of the president and librarian, with a list of the accessions to the library. It is an interesting publication.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 4.

Day by day the exhibition grows in interest by the addition or uncovering of new attractions; but still the vast buildings present many gaps, with preparatory indications, however, that they are soon to be filled. Although yesterday closed the second week of the fair, I saw great numbers of cars—not less than 20 in all—in various portions of the grounds and buildings, pouring out boxes and bales almost without number. Eight carloads arrived overland only three days ago, filled with Australian goods; which arrival, I am told, will complete that exhibit. When the end of receiving will be, none can tell but those who have power to put an arbitrary end to the admission of any further exhibits. Spain has not yet opened more than one-half of her goods in either of the four principal buildings. France is also much behind. In fact none, with but few exceptions, are yet fully ready with all their exhibits.

It will be readily inferred from the above why I have not yet been able to give comparative descriptions. It is now clearly certain that every foot of the area will be occupied throughout all the 70 or more acres of floor space available for exhibition purposes. In my second letter I think I set down the space at about 62 acres. I am now satisfied it will measure nearer 75—the amount which is claimed in the official publication—and which exceeds the area limit of the largest European exhibit by about 19 acres! Well, this exhibition can't be repeated, with all its pomp and circumstance, for at least a century to come, and so the great American people may be pardoned for making the most of it. No European nation will be likely to attempt to rival it during the present century. It won't pay them—it won't pay us. The great American Centennial is too big a thing to handle with much financial success. In fact, its value and importance ought not—can not be recorded in dollars and cents. Still we may be pardoned for giving

A Brief Financial Exhibit.

The Board of Finance, in its official exhibit under date of November 10th, 1875, reports receipts as follows:

State of Pennsylvania.....	\$1,000,000
City of Philadelphia.....	1,000,000
State of New Jersey.....	100,000
State of Connecticut.....	10,000
Miscellaneous donations.....	40,000
Stock subscriptions, about.....	2,200,000
Total.....	\$4,850,000

The board, under its original organization, was authorized to issue stock to the extent of \$10,000,000, but they estimated in their report of the above date, that \$8,500,000 would cover the necessary expense up to the day of opening. To the amount of \$4,850,000 already enumerated, Congress has since added \$1,500,000, and perhaps it is fair to estimate the sales of stock and other contributions since last November at \$750,000, which would give a total cash aggregate, at this time, of \$7,000,000, leaving but one and a half millions to be realized from the profits of the exposition and the sale of property which can be disposed of after it is over. But whatever may be the result—whether the cost reaches eight and a half or ten millions, there is no doubt that all the bills will be paid, although the stockholders may not receive anything in return for their investment. Probably very few ever expected any return—what they paid was from patriotic motives alone.

There has been no disposition manifested on the part of the commissioners to be niggardly in anything that would really tend to make the exhibition the success that it should reach; nor, so far as I can learn, has any "crookedness" been developed. The management, the contributors and the people at large will undoubtedly have the profound satisfaction, when all is over, to know that everything has been reached which could reasonably be expected to be realized from labor, skill and an honest expenditure of money. Everything has been done upon a liberal—nay, upon a grand scale, and the result, thus far, has been an undoubted surprise to the world, and a matter of national congratulations to the American people. Whatever may be the cost in dollars and cents, it may be set down as a not very extravagant price for the "universal Yankee nation" to pay for a grand Centennial "blow out." It won't come again in the next hundred years; will cost, even at the largest sum mentioned, less than two bits a piece for each man, woman and child in the land, aside from the traveling expenses and admission fees of those who enter into the fullest personal enjoyment of the occasion. Who cares, under the circumstances, for the paltry eight or ten millions which will be sunk in the enterprise?

Attendance and Transportation.

Since the rains to which I alluded in my last have been succeeded by clear and sunny skies, the streets and grounds and attendance have been wonderfully improved; and contrary to my anxiety a week ago, I find that a substantial pavement exists beneath the mud which then covered the main street approach to the Centennial grounds; but for much of a distance no sidewalk is yet visible over that thoroughfare. Although the attendance has largely increased there is yet nothing of the rush which was anticipated by the average

Philadelphian. As a consequence, ample hotel accommodations can still be found and at reasonable prices. A circular before me offers good accommodations at from \$2.50 to \$3.00 per day in a hotel within 200 yards of both the Pennsylvania railroad depot and the exhibition ground and where 1,000 guests can be accommodated, and the Grangers, at their encampment, are still accommodating all who come at even lower prices, hence no one need stay away from the Centennial on account of extravagant hotel prices.

It was estimated by the Centennial Commissioners that the paying visitors at the ground would reach an average of about 65,000 per day. This estimate is altogether too large, probably by about one-third, perhaps nearer one-half. Say the daily average will be 40,000. When that number is reduced by the very large attendance which Philadelphia chiefly furnishes, added to those who can reach the grounds and return to their homes every night by the railroads, it will readily be seen that the city with its special accommodations can easily accommodate all who come to stay. There will be no overcrowding except on a few special days, such as the Fourth of July and a few parade and society days.

At no previous world's fair have such extensive facilities been offered for the transportation of large numbers to and from the grounds, by street and other cars, as have been provided in Philadelphia. There are upwards of 250 passenger trains running in and out of the city every day, a large portion of which are timed for the special accommodation of visitors at the Fair. Excursion trains, morning and night, are thus run in almost every direction from 100 to 150 miles, at very low special rates. Passengers are put down at the grounds from New York in one hour and forty minutes, or at 9 A. M. (the opening hour), and taken back at 5 P. M., at which time the

torn from his person. The result of such unmannerly conduct has been to banish nearly all such display of individual nationalities from the grounds and the city, such persons, much to their inconvenience and dislike, having donned the conventional hat, coat, vest and trousers of the "universal Yankee nation." I have since noted only now and then a turban, supplemented with the flowing robe of some isolated Turk, more venturesome than most others of his countrymen.

The Foreign Commissioners and What they are About.

The foreign members of the Centennial Commission—the judges, experts, scientists, etc., are beginning to put in an appearance, and to accommodate them in their investigations the representatives of the press have been removed from their snug quarters and cosy rooms in the judges' hall to less convenient quarters in a large common room in a building erected for "the public comfort." The "press" of course, don't like the change; but they yield with as good a grace as possible to the convenience and possible needs of our foreign visitors and umpires. One half of all the judges have been very properly selected from representative men of foreign nations, and the liberal sum of \$1,000 has been appropriated to each judge, in payment of his expenses, and as some compensation for the time and labor which he will be expected to devote to the specialty to which he is assigned.

Count Dello Sala, the Turkish Commissioner, arrived in New York on Saturday last, as did also, on the same steamer, Sir Sidney Waterlow, M. P., one of the British Commissioners, others having preceded them.

The Germans have some of their best scientists and technical experts on the ground, who will study up the exhibition thoroughly, in all its useful and economical aspects. Prof. Herman, of the polytechnical school at Aix-la-

**HORSE-POWER FOR OPERATING PUMPS.**

machinery stops and the exhibition virtually closes, although all are not necessarily out until 6 P. M. The grounds are not open in the evening at all.

A large number of new cars will be put upon the New York road in a few days, which will consist of an ordinary carriage platform car, fitted up with temporary seats and covered with a cloth roof and curtains to keep out the sand and rain. These cars will be run from New York to the grounds in about two hours—arriving at 9 A. M., and returning at 5 P. M.,—at \$2 for the round trip. After the exhibition is over the cars will be covered and fitted up for regular passenger cars. The commissioners of the exposition, in connection with the various railroad officials, have displayed great energy and care in thus providing special transportation to meet the occasion, and to the credit of Philadelphia it should be known that her citizens have willingly seconded all such efforts, without manifesting any special disposition to make money out of visitors by rendering it inconvenient for them to make their trips to and from the city.

An Interesting Feature Lost.

One of the striking features connected with European international expositions, and especially so to citizens of this country, has been the brilliant uniforms of army and navy officers, the official robes of Eastern men of note, and the many-colored and multifarious forms and styles of garments worn by attendants and visitors from the different nationalities which have there assembled. A display of this character, somewhat limited in extent, was also expected at this exposition. Something of the kind was, indeed, seen on the "opening day," among the large number of Turks, Japanese, Chinese, Greeks, Egyptians, etc., who were in attendance, and the effect was duly appreciated and respected by the orderly people within the grounds. But no sooner had our enraptured visitors reached the public streets of the city than the bad side of Young America began to show itself in a very indecorous manner, and one seldom exceeded by even the ruffian conduct of San Francisco gamblers toward a newly arrived cargo of Chinese. These Centennial visitors were followed through the streets of the City of Brotherly Love, and for aught your correspondent knows, to the very doors of Independence hall, by crowds of idle boys and men, peered at with ill-mannered curiosity, saluted with rough epithets, and, in some instances, I am told, were actually assailed with ruffian violence. In one instance it is said the silken robes of a Chinese official were rudely

ing machine was invented by Thomas Saint, of London. It was seized upon and sold at enormously high prices by the combination monopoly; subsequently perfected and sold at prices within the reach of all, by Kimball & Morton; chief office and manufactory, Bishop street, Glasgow." On more particular enquiry, I learned further that it was in use in England more than 50 years before Elias Howe made his first model! This information rather staggered me; but as it was communicated by a very interesting young lady, I could not master sufficient courage to venture any doubt in regard to its correctness, so I left the history of the sewing machine to vindicate itself.

The sewing machine exhibit at the Centennial is, no doubt, by far the most perfect and complete that was ever made in any country. Seventeen different American companies are represented and four foreign ones—England, Scotland, Sweden and Brazil. The Scotch exhibitor, has already been named. Messrs. Newton, Wilson & Co., 144 High Holborn, London, make the finest and largest foreign exhibition. The machines in both the Scotch and English exhibits have all the novel improvements and accessories common to the American machine. The last named exhibit consists of some 50 machines, of 11 different grades and styles. One of these machines, "England's Queen," it is claimed, "presents some entirely new features, never before realized in a sewing machine." It can be instantly changed, "without stopping the machine," from the lock-stitch to the herring-bone stitch, and to oversewing. These changes are effected by simply turning a screw. The width and length of the stitch are also regulated at pleasure. A machine is also shown for sewing ships' sails.

This party also shows a "pleater," which gathers up the fabric into box-pleats, in front of the needle. The pleats, as they pass under the needle, being fastened to their places by stitching. It is claimed that this is the only pleater in use. It was invented by one of the firm, and has been patented in this country as well as in Europe. The English machines are made quite as ornamental, if not more so than the American. They also appear to be more substantial.

It has been often said and printed that the English have never made a practical success of the manufacture of the sewing machine; but we have here proof to the contrary, for this company, according to their circulars, at least, are manufacturing large numbers daily, many of which, after the home consumption has been supplied, are sold in various parts of Europe, South America, Africa, India and the British colonies. They have three times enlarged their works to meet the increased demand for their machines, and are now making a fourth enlargement, which, when completed, will enable them to turn out 1,000 machines each week.

The Brazilian and Swedish machines are all very plain, but substantial in their make, and are not calculated for fancy work.

W. B. E.

Centennial Grounds, May 23d, 1876.

A Simple Pumping Power.

We present our readers herewith the illustration of a novel horse power for operating pumps, the invention of Mr. D. T. Gillis, late of Stockton, the inventor of several other ingenious and useful devices. The horse power, it will be seen, consists of a centrally pivoted walking beam, one end of which is connected with the pump rod by a pitman, while the opposite end is connected with a crank wheel by a similar pitman. This crank wheel is secured upon the end of a horizontal shaft, which is supported by a suitable standard near the wheel. The outer end of this shaft has a large traction wheel mounted on it, and the horse is hitched to the shaft near the traction wheel. As the horse travels around in a circular track, the traction wheel rotates and the motion is transmitted through the crank wheel, oscillating beam and pitman to the pump rod. This arrangement is extremely cheap and simple, and cannot help but be effective.

The horse power is manufactured by the Sweepstakes plow company, and parties desiring to learn further particulars can address F. A. Hill, San Leandro, Cal.

PAID OFF.—The Consolidated Virginia company have paid their workmen over \$81,000, the Belcher \$62,000, and other mines in like proportion. More money has been paid out this month than any month this year, as there are an unusual number of men employed in making surface improvements, as in putting up the new machinery at the Savage, Hale and Norcross, Gould and Curry, the new stamp mill of the California mining company, the new passenger depot of the Virginia and Truckee railroad company, and many other operations on the surface in all parts of the town.—*Territorial Enterprise.*

The German commissioners, Althons, Broja, Diefenbach, Richter and Koob were shown through the works at Hell Gate on Wednesday, 17th inst. They displayed great interest in the undertaking, inquiring particularly into the subject of rock-drilling as practised there, and in conclusion expressed themselves much pleased at the way in which the work had been conducted, and thought the experiment of a combined blasting operation, as about to be practised there, could not fail to be of the greatest scientific interest.—*Engineering and Mining Journal.*

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

BEFORE PAINTING YOUR HOUSES

Send for Sample Card and Circular and Carefully Examine the

AVERILL CHEMICAL PAINT,
MIXED READY FOR USE.

This Paint is prepared in liquid form, BEADY FOR THE BRUSH. It requires no addition of oil or spirits. It is composed of the best materials known to the trade—Pure Linseed Oil, Strictly Pure White Lead, Pure Zinc, and the finest of coloring matter for tinting. It is the **BEST, CHEAPEST, MOST DURABLE AND BEAUTIFUL PAINT IN THE WORLD.** Is just what is wanted by every farmer, mechanic and everybody who has a house, fence, barn, or wagon to paint. Requires no skilled labor, as any one can apply it who can handle a brush. It is put up in cans of any required size, from a quart to five gallons, and is sold by the GALLON. It gives a firm, elastic and brilliant glossy finish, and will neither crack, peel or wash off, like most paint in common use, but is proof against rainstorms and all action of the elements. Buildings painted with this paint five years ago look fresh and like new to-day and will need no more paint for years. Of no other paint can this be said and proved.

The Averill Chemical Paint Company supply a long-felt want. They not only furnish a Paint more lasting, handsomer, and at the same time cheaper than the best of others, but it is in a liquid form—white and all the fashionable and most exquisite shades—ready for the brush. So that farmers, in fact everybody, can be their own painter if necessary. Indeed, all the buildings upon which the Averill Chemical Paint has been applied, are marvels of beauty.—*Christian Union.*

We know of no subject of such importance to householders as that of a good, handsome, durable paint for their dwellings. Within the past few years we have watched the progress of the Averill Chemical Paint and have had frequent opportunities to test it fully. We think it just the article to supply the need, and give it our hearty endorsement.—*N. Y. Independent.*

From the Thousands of Testimonials sent us, we select the following, which we present for your careful consideration:

A PAINT FOR FARMERS.—Prof. J. B. Turner, Jacksonville, Ill., is a man of great practical knowledge and experience; hence, we attach a great deal of value to the following, from his pen, which we find in the *Prairie Farmer*:

"Some two years ago I sent for and got from a barrel to a barrel and a half of Averill Chemical Paint, of light dun color, which I thought would suit me well enough for all work—houses, doors, blinds, fences, bee-hives, wagons, tools and all. I put two coats upon my residence here, and run over three or four of my smaller farm houses on my farms. With what was left I painted my bee-hives, wagons, wheelbarrows, rollers, harrows, fences, etc., and on all these buildings, implements, tools, gates, etc., the paint is as hard and glossy to-day, as far as I can see, as it was a month after it was put on, and bids fair to hold its own at least for five years to come, (if not ten of them,) better than ordinary white lead and oil does for even two years.

"I have watched it now for about two years with interest and care, and have never found a single spot where it peeled, cracked, or chipped off, as our other paints do. Others who have used this paint like it equally as well. But the point is, I can take one and the same keg and brush, and go over all my buildings, wagons and tools, with no needless waste of paint, brushes or time. It is quite as good for inside finish, as it leaves a coat that shines and washes like glass."—*Moore's Rural New Yorker.*

THE AVERILL PAINTS.—In reply to some inquiries of our readers, we would state that we have given these paints, prepared by the Averill Chemical Paint Company, a full trial, and they appear to possess all that is claimed for them; spreading easily, adhering well, drying soon, and imparting handsome shades of color to the surface covered. Farmers and others who do their own painting, may avail themselves of the convenience of purchasing these paints, of any desired shade, already mixed for use, at a very reasonable price.—*Cultivator and Country Gentleman.*

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your letter I have to state that for more than six years I have dealt in and used your paint. I have during that time carefully observed its application and use, and from practical knowledge can certify to its unrivalled excellence. During my six years' acquaintance with it, there has not come to my knowledge a single instance of failure in any case where it has been used. All to whom I have supplied it unite in commending it for its superior claims over all other paints now in use. The Averill Paint externally used, or, in other words, exposed to the action of the weather, neither rubs off nor changes color, as do other paints, and will retain its freshness and adhesive property for years. Pure lead and oil will in a short time become dry, and are easily rubbed off; the loss of oil leaves the lead in a dry, oxidized state. As a matter of economy the claims of the Averill Chemical Paint to popular appreciation and general use are beyond question. A house properly painted with it once will be better preserved, and present a neater appearance at the expiration of seven years, than it would if twice coated with lead and oil paints now in use. There can be no question, then, that to use it is both labor-saving and economical. So well assured and convinced am I of its established right to this distinction over all kinds, that had I fifty houses of my own to be painted, the "Averill" alone should be my choice and used.

Yours, very truly, S. J. ALDEN, Druggist.

PLACERVILLE, October 7, 1875.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your note of the 13th inst., I willingly state that the work done by you in painting the exterior of the North Hall or College of Letters is in every way satisfactory, and the appearance of the building since it was painted excites the favorable comment of all who have seen it. As I have had occasion to use the Averill Paint before, my experience has been such that I prefer it to any and all others when properly applied. I am very truly yours,

ROBT. E. C. STEARNS.

Hope Quicksilver Mining Company.—Lo-

cation of principal place of business, San Francisco, California. Location of works, Unsubdivided Mining District, Sonoma County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 12th day of May, 1876, an assessment (No. 1) of three (3) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, room 2, No. 408 California street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of June, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 10th day of July, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JACOB HARDY, Secretary.

Office, Room 2, No. 408 California street, San Francisco, Cal.

Manhattan Marble Company of Califor-

nia. Location of principal place of business, San Francisco, Cal. Location of works, Oakland, Alameda Co., State of California.

Notice is hereby given, that at a meeting of the Directors, held on the 23d day of May, 1876, an assessment (No. 9) of three dollars per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary of the company at his office, Nos. 13 and 15 Fremont street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of July, 1876, shall be deemed delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 17th day of July, 1876, at 12 o'clock M., to pay the delinquent assessment, together with costs of advertising and expenses of sale.

L. L. ALEXANDER, Secretary.

Office, Nos. 13 and 15 Fremont street, San Francisco, Cal.

Mariposa Land and Mining Company

of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 5), levied on the second day of May, 1876, the sum of \$1.00 amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the second day of May 1876, so many shares of each parcel of said stock as may be necessary will be sold at public auction, at the office of the Company, room 33, Nevada block, 363 Montgomery street, San Francisco, California, on Friday, the thirtieth day of June, 1876, at the hour of one o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

LEANDER LEAVITT, Secretary

Office, Room 33, Nevada block, 363 Montgomery street, San Francisco, Cal.

Taylor Mill and Mining Company.—Principal place of business, City and County of San Francisco, Cal. Location of works, Garden Valley Mining District.

Notice is hereby given that at a meeting of the Board of Directors, held on the fifth day of May, 1876, an assessment of twenty (20) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at his office, 601 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-first day of June, 1876, will be delinquent and advertised for sale at public auction, and unless payment be made before, will be sold on Thursday, the sixth day of July, 1876, to pay the delinquent assessment, together with costs of advertisements and expenses of sale.

SAMUEL S. MURPHY, Secretary.

Office, 601 Montgomery street, San Francisco, Cal.

Tremont Mining and Milling Co.—Stockholders' Annual Meeting. The regular annual meeting of the stockholders, for the election of officers and the transaction of business, will be held at the company's office, No. 402 Front street, room 8, in the city and county of San Francisco, on Wednesday, June 14th, 1876, at one o'clock P. M.

MARK T. ASHBY, Secretary.

Empire Tunnel and Mining Company of Utah.

At a Directors' meeting of above company, held on the 16th inst., it was resolved that a meeting of stockholders of the company be convened on Monday, June 19th, 1876, at the office of the company, 635 California street, to decide upon a proposition to increase the capital stock of the company from three hundred thousand (\$300,000) dollars, divided into thirty thousand (30,000) shares of ten (10) dollars each, to seven hundred and fifty thousand (750,000) dollars, divided into seventy-five thousand (75,000) shares of ten (10) dollars each.

Schofield's

SULPHURET CONCENTRATOR.

THE BEST MACHINE IN USE FOR
 SAVING SULPHURETS.

No Power Required to Run it, and only a Small Stream of
 Water under a Light Pressure.

ECONOMICAL,

EFFECTIVE,

DURABLE,

AND SURE IN OPERATION.

The especial attention of parties erecting new mills is called to this
 Valuable Improvement.

WE GUARANTEE THAT THIS MACHINE WILL SAVE NINETY PER CENT. OF ALL THE SULPHURETS
 IN THE ROCK AT A MERELY NOMINAL EXPENSE. IT HAS NOW STOOD THE SEVERE
 PRACTICAL TESTS OF OVER A YEAR'S WORK AT DIFFERENT MILLS
 ON THIS COAST, AND HAS BEEN EMINENTLY
 SUCCESSFUL IN EVERY CASE.

The following letters, from practical men who have used this machine, will show to
 those interested what it has accomplished:

BANDERETA MINE,
 Mariposa County, Feb. 7th, 1876.

CHAS. SCHOFIELD, Esq.—Dear Sir: We have been using your Concentrator at our mill
 about six months, and find that it saves over 90 per cent. of the sulphurets contained in the ore,
 and all of the amalgam and quicksilver which escapes from the battery. The machine is simple
 in construction, perfect in operation, and requiring no power to run it, is very economical. I
 can confidently recommend it to all mill men as the best and cheapest Ore Concentrator now in
 use. Yours respectfully, LEVI NOEYS, Superintendent.

NONPAREIL GOLD MINING CO.'S WORKS,

Deer Flat, Tuolumne County, Cal., April 12th, 1876.

MR. CHARLES SCHOFIELD—Dear Sir: It is four months since the Sulphuret Concentrator
 you furnished our company's mill with was first put in operation, and during the past three
 months has been nearly in constant use. The men attending the Concentrator having acquired
 by practice a thorough knowledge of its workings, there is nothing more to be desired; it is
 perfect. A number of mill men have examined the Concentrator and its workings, and pro-
 nounce it the most simple in its construction, perfect in its work, and cheaply run of any they
 had seen. If you think by showing this it will assist you in disposing of your Sulphuret Con-
 centrators, you are at liberty so to do, as it will afford me much pleasure in having contri-
 buted my little mite towards rewarding true merit. Hoping you will meet with complete success,
 I remain yours truly, JOS. J. DOPRAT, Superintendent.

CON. ALABAMA M. CO.,
 Tuolumne County, May 1st, 1876.

C. SCHOFIELD, Esq.—Dear Sir: The Concentrating Machine recently purchased of you is
 now in active operation, and we are highly pleased with it. It saves over 90 per cent. of our
 sulphurets, and is run with very little expense. We could not afford to be without it, and can
 safely recommend it to all mill men as the best and most economical machine in use.

M. S. McCONNELL, Superintendent.

WASHINGTON MINE,
 Mariposa County, Cal.

CHAS. SCHOFIELD, Esq.—Dear Sir: Having had one of your Double Rigged Concentrators
 in use now at this Mill for over a year, I take this opportunity of informing you that it is far
 superior to the old English Buddle we have been using for the last four years, not only in a
 saving of labor, but having a less waste of sulphurets in washing.

We have the machine connected with the tail sluice, and receives the sand and water direct
 from the batteries; without any handling, and it does the concentration for the 20 stamps easy,
 with a loss of less than 10 per cent.

Two Chinamen do all the work required—one night and the other day—working 12 hours
 each, and get out about a ton each day, thus concentrating 30 tons into one, at a cost of less than
 four dollars. As the cheapest, most economical and best working Concentrator I know of I can
 recommend it to others without any hesitation.

Yours truly, GEO. E. WEBBER, Jr.,
 Superintendent Washington Mining Company.

MR. SCHOFIELD—Dear Sir: Having carefully examined your Concentrator, which I have
 seen in successful operation at the Francis Company's Mill and also at the Benton Mills, on
 the Mariposa Estate. I have no hesitation in saying that it is the most valuable Concentrator
 I have met with during my long experience as amalgamator in this country. Its manner of
 catching quicksilver and amalgam is thorough and complete, and it saves the sulphurets clean
 and with a loss of less than ten per cent.

Yours respectfully, L. BURDOW.

MR. C. SCHOFIELD—Sir: I have worked one of your Sulphuret Machines at the Benton
 Mills about 30 days, and am satisfied it is the best machine for saving amalgam and sulphurets
 ever used on the Mariposa Estate.

The following testimonial is from the well known mining expert, PROF. J. E. CLAYTON:

CHAS. SCHOFIELD, Esq.—Dear Sir: Having followed the business of mining engineering
 for upwards of 30 years, and having had in this connection much to do with regulating ma-
 chinery for saving gold and concentrating sulphurets, and having in nearly every mining camp
 on the Pacific Coast examined the various kinds of Ore Concentrators in use, I will say that I
 have never seen anything half as cheap and simple in its construction, scientific in principle
 or effective in operation as your machine. J. E. CLAYTON.

Machines can be Furnished at Short Notice. In all Cases we Furnish the
 Concentrator Complete, Set it Up, and Instruct the Buyers as to
 the Proper Way of Managing It.

Burns Wood or Straw without change, and Coal by changing two plates. Took the Premium at the
California State Fair, 1875, as the Best Straw Burner.PIONEER BUILDER OF THE FIRST PORTABLE THRESHER ENGINE ON THE PACIFIC COAST, 1861
PATENTEE AND BUILDER OF THEBEST PORTABLE STRAW OR WOOD BURNING THRESHER ENGINES, 1878.
Send for Testimonials and Price to

JOSEPH ENRIGHT, San Jose, Cal.

Ms. J. ENRIGHT—Dear Sir: The Straw Burning Engine I bought of you, and which was used in Yolo
county, has given us perfect satisfaction. It is everything you represented. We have had no difficulty in
generating all the steam required, and the amount of straw consumed can hardly be missed. We find it much
safer, on account of fire, than a wood burner. Many persons, both threshers and farmers, have come to see it
run, and all express themselves highly pleased. The opinion of all was, that it is just what we need, being
safe and economical. H. M. LARUE.

Cook's Patent Automatic Boiler Feeder & Regulator.

Economy in Operation. Absolute Safety from Explosion.

SIMPLER THAN A PUMP, AS IT REQUIRES NO ATTENTION.

ECONOMY IN FUEL.

Entirely Automatic, Reliable & Durable.

Cook's Automatic Boiler Feeders

WERE AWARDED THE HIGHEST PREMIUM
OVER ALL MACHINES EXHIBITED AS
BOILER FEEDERS AT THE CIN.
INNATI EXPOSITION AND
THE ST. LOUIS FAIR.

The cuts show the operation of the Feeder. It was described in detail in the MINING AND SCIENTIFIC PRESS of May 20, 1876.

This Feeder will discharge from 40 to 200 gallons of water at one movement, where a pump would require hundreds of strokes to do the same work.

The water is kept exactly at the proper line, whether running fast or slow, without attention from the engineer.

Feeders, Heaters and Regulators Combined are made on this principle. Simple and economical.

The control of feeding water to the boiler, is taken out of the hands of the engineer and left to governing natural laws.

These Machines are now introduced on this coast for the first time, although they are extensively used in the Eastern States. They supply the boilers with great regularity, and keep the water at exactly the same level. As a protection against explosion they are simply perfect, leaving nothing to be desired.

ONE OF THESE FEEDERS CAN BE SEEN IN OPERATION AT THE PACIFIC IRON WORKS.

Address.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 5.

The Board of Judges

Have completed their organization, and are now getting down to the vigorous work before them. They are fast becoming acquainted with each other and are constantly passing from one building to the other to examine thoroughly and fully comprehend the merits of the various specialties upon which they have been commissioned to express an opinion. It is understood that they have adopted a badge which will soon be placed upon their persons, and by which they will be more readily recognized by exhibitors and visitors. Such a distinction would seem to be not only somewhat out of place, but exceedingly annoying as well, from the natural effect it would have of drawing crowds around them when passing through the grounds, and especially while inspecting exhibits, a duty which one would suppose they would desire to perform with as much privacy as possible. The report may not be correct, but at all events it is so circulated and published in the city papers this morning. In one of my letters I mentioned that each judge receives \$1,000 in compensation for his services. Such compensation was so fixed, at first, all around; but recently the pay of the American judges has been reduced to \$600. The Board comprises 125 American judges, who have been carefully selected by the Centennial Commission, and divided into 28 groups. To these have been joined 100 foreign judges, who have been appointed by the representatives of the several foreign governments exhibiting at the exposition. They occupy for their sessions a large and commodious building, containing a large general hall and a sufficient number of small committee rooms to accommodate each of the several divisions or groups. Mr. Scott, of San Francisco, has not yet appeared, but is expected about the 10th of June. Gen. Naglee, of San Jose, has reported his inability to be present on account of sickness in his family. Gen. Gibbons, U. S. A., of Montana, cannot be found; he is out hunting Indians, and Henry Mitchell, of Cincinnati, has been appointed in his stead. About 100 of the foreign judges are already on the ground. The Sunday Opening Question, Etc.

The question of opening the Exposition on Sunday has created a large amount of interest, pro and con. The Commissioners, or a large majority of them, are decidedly opposed to opening; but there is a large element in the city who favor it. They desire the opening, ostensibly, to accommodate the working masses; but from what I can learn it is really a pecuniary matter with them. It will bring thousands into the city on Sunday who now stay away, and largely increase the receipts of the exposition, whereby there will be a better chance for holders of Centennial stock to get a dividend, of which there is now a very slim chance. There is something like a million and a half of Centennial stock held in and near the city, for which the holders are very anxious to get at least a partial return. Several large public meetings have been held to induce the Commission to change their decision. It is said that the one held in and about Musical Fund hall last Saturday evening was attended by 5,000 people. But a quiet little demonstration made by the Presbyterian General Assembly, held last week, and headed by Dr. Prime, seems to have inspired the Centennial managers with new courage to hold out against the popular clamor. It is to be hoped that they will persevere in this decision. Any change therefrom would bring a scandal upon the Exposition and a national disgrace upon our people. I believe the Pacific coast Commissioners are all right in this regard. Indeed but very few of either the managers or the exhibi-

ors favor any change. If the buildings were opened but very few of the exhibitors would uncover their stands or operate their machinery. Six days in the week is as much time as they can give the dear public—considering that they are enlisted for a six months' campaign.

Machinery Hall.

Solomon was undoubtedly a wise man—for his day; but if he had lived in the present age of the world, and been permitted to note the progress of improvement during the last hundred years, he certainly would never have written, in regard to the physical devices of men, "There is nothing new under the sun;" for no man can take a walk through this vast building, and examine the fourteen acres of machinery here displayed, embracing many hundreds of separate and distinct machines, to say nothing of the infinite of their modifications, without being fully convinced that the past century has devised at least a few things that would be "new under the sun," even to the builders of Solomon's temple, were they here to see. But then the sacred writer evidently had in mind the moral "crookedness" of his fellow men rather than their physical devices. Certainly he had never contemplated an "international exposition," or perhaps any machine other than the potter's wheel or the simple device by which his daily amount of "corn" was reduced to flour.

In no part of all these immense grounds is it made so apparent as in machinery hall that life is indeed real and earnest. It is here and

useful and practical results of man's industry as displayed in the main exhibition building. To the mechanic and inventor no such field of study and research has ever before been presented. The handiwork and the skill of some 20 of the leading nationalities of the world are here represented—the whole forming an aggregate which is perfectly bewildering to the uninitiated.

The Structure and Dimensions of the Hall.

The building in which these marvelous results of human industry are collected is itself a marvel. It is 1,403 feet in length, 360 feet in width, with an average height of about 60 feet. Our readers are familiar with its general outside appearance from illustrations already given, which are strictly correct in every particular. Eight main lines of shafting are provided for operating the machinery which has been placed within, which, with the counter shafts, and those in the "hydraulic annex," must measure over two miles in length—all driven by a single engine, the great double-acting upright Corliss. Each main line is capable of transmitting 180 horse-power. The main entrance is upon the east end or right hand of the diagram as shown herewith. The hydraulic annex, as shown, has been constructed for the special convenience of the immense array of pumps which are here shown from Europe and America and of all sizes from a common hand pump to a mammoth rotary which is arranged to represent a miniature Niagara in the shape of a waterfall 30 feet high, 36 feet in breadth, with a weir depth of

exhibits, the very small chance of effecting sales, and the much smaller employment of minor machinery in English and European shops to what is used in this country, the proportionate foreign exhibit may be considered very creditable.

In the main and much larger building, however, the proportion is reversed, for there the United States exhibit occupies only a little more than one-quarter of the entire area. But then, as an offset to this disparity, the United States occupies the whole of the Government building, 480x360 feet in dimensions, also the shoe and leather dealers' building, in which all that class of our exhibits are made.

In agricultural hall nearly one-half the space is occupied by foreign exhibitors; and in the art gallery fully three-quarters. Hence it will be observed that the average amount of foreign display must not be judged by what is shown in the diagram to-day.

The number of foreign nations represented in machinery hall is 15; in the main building, 30; in agricultural hall, 18, and in the art building, 18. We purpose to give diagrams of each of the above buildings, showing the proportion of area occupied by each nation, and its relative position to all others. These diagrams will be found very convenient, in fact almost indispensable, in forming anything like an accurate conception of the display from any description which can be written.

The Individual Exhibits.

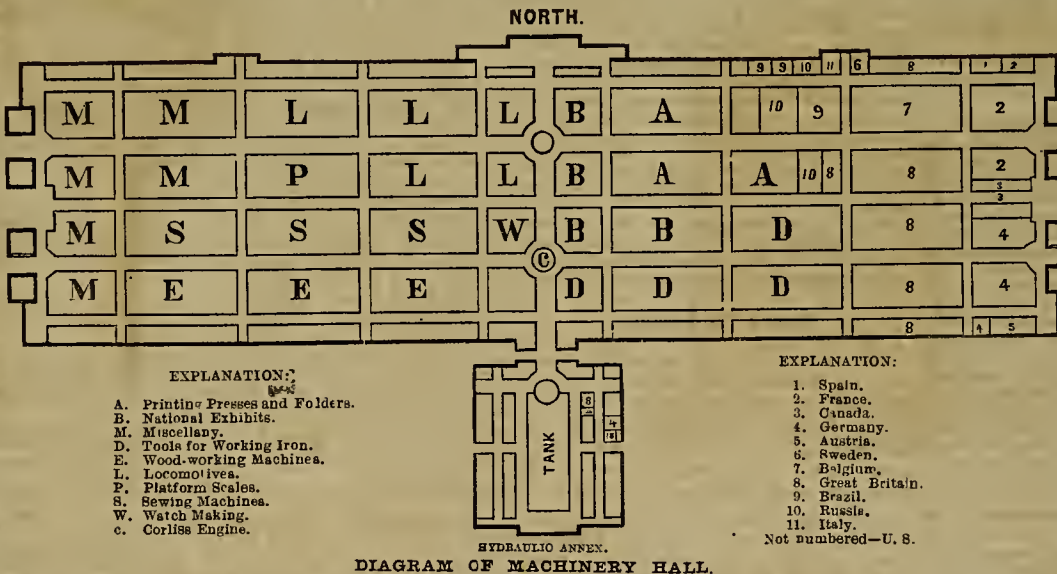

We come now to the individual exhibits, and we will endeavor to give as clear and comprehensive a view of them as possible in the limited space at our disposal. Entering the building by the central entrance at the east, the visitor first encounters the foreign exhibitors, who have very properly been accorded the place of honor in position. The first thing which arrests the attention is the exhibit of our neighbor on the north, France.

Passing a little to the right—keeping our diagram in view—we come to the French section. The machinery consists chiefly in some hydraulic presses not shown in operation, a set of machinery for preparing chocolate and another for manufacturing confectionery in actual work, as is also another near by for cutting and stamping, from sheets, fancy toilet soaps. Both confectionery and soaps are sold to ready buyers, and the proprietors will evidently make their exhibit pay. The heavy exhibits of France consist chiefly in a few forged car and locomotive wheels, shown in sections in process of man-

ufacture, and water pipes covered and protected from decay by a heavy coating of sand and asphaltum. Several machine lithographic presses are also shown in motion, but not doing work. France excels all other countries in producing nice and cheap pictures, and of course she should show how she makes them.

ENORMOUSLY RICH.—We saw some specimens of gold quartz from Melones mine, Carson Hill, Calaveras county, and we confess something like gold fever crept over us. We actually never saw anything like it. It is from a pay streak of $4\frac{1}{2}$ inches in width, and assays about \$100,000 per ton. The balance of the ledge, 25 feet in width, assays from \$50 upwards, all good milling ore, and the depth of 180 feet attained shows that the ledge is a constant one. Gold mining is looking up.

DISSATISFIED STOCKHOLDERS.—Under this heading our daily contemporaries bring notices of a number of meetings held in this city by dissatisfied stockholders. Woodville and the artful manipulations of its manager had almost scared the balance, but Niagara has gained a victory, and a number of others will readily follow. We are afraid that impetuous stock sharps for mine managers will soon be at a discount.

in the government building, near by, where a large amount of machinery has also been placed, that people come most to study. Here is where the thoughtful among them most frequently gather into little companies and with knit brows enter into the careful examination of the peculiar mechanism by which the various and wonderful results of industry and skill are wrought out. Especially is this the case wherever machinery is engaged in "making things," such as watches, curiosities in glass, metallic cartridges, letter envelopes, weaving portraits, rifling gun barrels, turning gun stocks, and by machinery cutting out the ornate and irregular mortices for receiving the locks, casting type by machinery, etc., etc. Perhaps the most marvelous and really useful exhibits in this building are the two great printing press rivals—the English Walter and the American Bullock presses. The great number of spectators observing and carefully studying all these and various other processes demonstrate the little that is known by the average public as to how the various familiar objects of everyday use are made, and yet how eager nearly all are to acquire such information; and it may here be remarked that this kind of interest affords a gratification of quite as high an order, and far more useful than that which comes from viewing and studying the beautiful creations of genius as shown in the art gallery, or the more

four inches, which gives a nearly continuous sheet of water from top to bottom of the fall. This result is produced by a double rotary pump, and forms quite a feature of itself. The annex is 208x210 feet in extent, and is filled almost entirely by pumps, receiving their water from and discharging the same into a large central tank as shown, 106x60 feet in area.

Two railroad tracks are laid the entire length of machinery hall, through the two principal avenues as shown, and one along, just outside the southern wall. These tracks connect directly with the Pennsylvania railroad, and upon them nearly all the ponderous machinery has been introduced into the building, and lifted into place by the aid of two heavy cranes in the English exhibit, which will be noticed in their proper connection.

Relative Proportion of Area Occupied. A close examination of the diagram will enable the reader to form a very accurate idea of the proportionate amount of area occupied by the different nationalities in this hall. The sections designated by figures are occupied by foreign nations, those by letters and those by blank are occupied by the United States. The foreign exhibitors occupy only about one-quarter of the interior space. It was expected that a larger space would have been taken from abroad, but when we consider the distance of transportation and expense involved in such

CORRESPONDENCE.

Some of the Mines of El Dorado County.

[By our own Correspondent—No. 3.]

In my last I stated that some attention would be given to hydraulic, cement and gravel mines lying south of the American river (south fork), in El Dorado county. At Placerville the El Dorado Water and Deep Gravel Mining Company

Have three claims, the Excelsior, Spanish Hill and White Rock, and are running on a vast scale and must be doing a splendid business. The Excelsior alone paid at the last clean-up at the rate of \$1,000 for every ten hours' run. This claim is running six 15-inch Craig giants; main pipe 30 inches and distributing pipes 22 inches and 15 inches respectively. The flumes are four and six feet in width. Mr. F. A. Bishop, the superintendent, has discovered a new system of operating derricks which is now in successful working order at the Excelsior mine. As he will probably take steps to secure a patent, little information, perhaps, ought to be given concerning it at present; this much, however, may be said: that it is likely to prove valuable to the mines of the State. The reel remains fixed while the masts are movable. The company's new ditch is now nearly completed. It is four and one-half feet in width at the bottom, 15 feet on the top, and six feet deep, capable of carrying 5,000 inches of water. It commences at Cedar creek on the south fork of the American river, and is forty miles in length. The number of men usually employed on ditch and mines will probably reach two hundred. The average earnings thus far have been 15½ cents per inch.

Messrs. Goyan & Dickerhoff have been working a cement mine here for at least 15 years, and have done well so far as could be learned.

The Robinson Gravel Claim,

near Smith's flat, employs ordinarily from 40 to 50 men, and has yielded from \$250,000 to \$400,000 within the past five years, according to the best information that could be obtained.

Oak Ranch Claim,

(Lucas, Meyers & Co.), not far from Smith's flat, has been worked for the last 16 months, and has turned out well. The company have two mills of 10 stamps each, one of which has turned out as much as \$1,000 per week. They give employment to about 40 men.

Mr. Blakeley, at the Five Mile house, on the Placerville and Carson City road, is taking out a considerable amount of coarse gold from his hydraulic claim. Mr. Goldner has also commenced work near by with very flattering prospects.

Two or three companies were found at work at Negro hill, engaged principally at present in running prospecting tunnels.

The Park Canal and Mining Co. (Limited)

Have a very valuable property, located near Pleasant Valley, and admirably situated for advantageous working. They have Government title to 160 acres, 92 of which are deep gravel, with a depth of bank from 60 to 250 feet. Character of gravel, elongated and little worn. On bottom are 30 feet of drift corresponding to description of blue lead in Raymond. The gravel pays from 20 cents to \$1.50 per cubic yard; or 20 cents per inch of water used. The tunnel is 280 feet. The ditch to supply mine carries 2,000 inches from Park creek; pressure on pipes 190 feet; outlet over 400 feet; tail flume, 3 feet wide, 800 feet long, with series of damps to break the cement and liberate the gold; employ two Giants and 1,800 feet of 15 inch and 11 inch pipe. The canal department is very extensive, embracing 281 miles, including three main lines and branches. Capacity of main lines 1,500 inches. Canal supplies 2,200 acres of deep gravel ground, the district supplied being between Webber creek and the Cosumnes river, and extending from the Sierras to within 14 miles of Sacramento.

Not less than five quartz mills are supplied from this quarter, water being furnished to miners at 6½ cents for 10 hours, and to ranchmen at 25 cents per inch for season, or at \$10 per acre.

Improvements are now in the course of construction—the details of which must be omitted—estimated to cost \$160,000. At this claim may be seen an improved stop-gate, patented by Mr. J. M. Crawford, through the agency of Dewey & Co. The same may be seen at the Excelsior mine, Placerville, after the designs of Mr. F. A. Bishop, in which, when open, the water forms a continuous stream, and the power or pressure is increased over five per cent.

Hydraulic Mines South of the Cosumnes.

In the vicinity of Fair Play, there is a considerable amount of prospecting going on, and there is a good opening for more capital. Mr. Claybrook, on Bear hill, informed me that his races prospect fully as well as former ones that paid \$15 per day to the man. Mr. Beillecks is also at work here adjoining ground that paid handsomely, not less than \$3,000 having been taken out within two months, with the aid of one or more partners.

The Mansfield Hydraulic Mining and Ditch Co., A. D. Allen, superintendent, are at work in Slug gulch. Their tail race extends through a

tunnel 780 feet long. They own a ditch eight miles in length, the water being taken from the South fork of the Cosumnes, and contemplate extending it five or six miles further to the Middle fork. The full value of this property will probably be determined by another season. Great hopes are entertained here that it will prove remunerative.

A Fact for Science.

Captain Claghoro, a very intelligent miner at Fair Play, informed me that he found in a tunnel, 1,000 feet from the mouth and 200 feet from the surface of the hill, in Slug gulch, a joint-bone of some animal, imbedded in the cement, near the bedrock, with a dozen different strata of cement and pipe-clay overlying. There is a depth of soil above the gravel of at least 100 feet, where a sugar pine is now standing, six feet in diameter. It must have been some time since that animal was drowned in that old river channel.

The Carrie Hall Hydraulic Mining and Water Company's Claim,

Owned by Messrs. Hall, Bradley & Co., is located in Henry's diggings, three miles southwest of Grizzly flat, occupies an area of 250 acres, and is admirably situated for any amount of desired fall, not far from the Middle fork of the Cosumnes. They own a ditch eight miles in length. Over \$1,000,000 has been taken out of the gulches running into the hill where they are at work.

M. E. Hall, superintendent, contemplates running a drift into the hill with the view of prospecting the channel, having already reached the rim, and from all the surroundings has every reason to hope for a rich return for the amount expended.

Mr. Richardson is opening a claim at French flat, near Indian diggings, and is developing a fine body of gravel which is exceedingly promising. The largest operations in this kind of mining in Cosumnes township were found at Indian diggings. Mr. Murry has been at work here for the past ten years with a small hose, and has made it profitable. His facilities being now greatly increased, his prospects for a more ample yield are said to be excellent. Messrs. Brinrowes and Pack have been working here for some time on a small scale, with good returns. They have taken out with a common hydraulic hose, one and a half inch nozzle, using only 75 inches of water, as high as \$1,450 in a single month.

The Cedarville Water and Gravel Mining Company's Claim

At this place covers an area of 350 acres, and is looked upon as a very valuable piece of mining ground. There is ample dump room for all time to come. They are running two little giants under pressure of 300 feet. They use about 1,000 inches of water. The flumes are three feet by two feet in the clear, having a fall of one-half inch to the foot. The claim has been prospected, as I was informed by the superintendent, by six different tunnels. One of these has been extended into the hill 1,800 feet, showing a bed of gravel 108 feet deep, paying 75 cents per cubic yard, as drifted out. They are now running with flumes to reach the same deposit prospected by the tunnel. Here we noticed a large lamp manufactured by Messrs. Brittan, Holbrook & Co., of your city, that lights a bank 200 feet high and 300 feet ahead, enabling the men to work continuously for 24 hours.

When I reach Georgetown you will probably hear something of the quartz, gravel and porphyry claims lying between the south and middle forks of the American river. K.

Beyond the Sierras.

Editors Press:—One of the most beautiful valleys in the world is that where I now rest. It is walked on either hand by the Sierra Nevada on the west and the Inyo mountains on the east, and in some places appears completely girdled by these two great chains. It is, in itself, a high table land, having been ascertained by exact measurement to be 4,340 feet above the sea, while the higher peaks are nearly 11,000 feet. The grand effect of these snowy summits, standing as they do against the deep blue that might rival in clearness the famed Syrian skies, can hardly be imagined. As we gaze into their depths, shadowy caves, sparry grottoes and crystal halls open to the sight, and we wander away through scenes of unimaginable peace and beauty. Indeed, the mountain scenery of this region could not well be surpassed.

The valley itself is about 100 miles long, and from 10 to 15 wide, and is watered in its whole extent by Owen's river, a very winding stream, with a deep and narrow channel, that carries water enough through the year, if properly distributed, to irrigate the whole valley. This stream is said to bear a striking resemblance to the Jordan, while Owen's lake, into which it empties, is in some of its characters like the Dead sea, for it has no visible outlet and contains no fish. Indeed, the general character of the scenery would remind the traveler of Palestine or the Holy Land, but the lively little steamer that plies on the lake gives to the scene a modern, familiar look.

A few miles from the lower end of the lake is Lone Pine, which, it will be remembered, suffered much by the great earthquake of 1872.

It is now the depot where the business interests of the neighboring mines are chiefly transacted. The village is spread over a great deal of ground and has an excellent hotel, kept by Mrs. Eames, whose refined manners and womanly kindness will not soon be forgotten. Here it may be said that the Cerro Gordo mines, about 20 miles east of Lone Pine, which for the last 18 months have been lying idle on account of litigation, are now running, with two furnaces in full operation, and under the new corporation they will probably double their products within a year.

A morning ride of 16 miles through a vast level of sage brush, with here and there, as there might be almost everywhere, fine ranches, we arrive at Independence, the seat of Inyo county. Though only nine years old, this little town has already some marked advantages, among which are the Blaney hotel, which, in the general good taste of its appointments and the excellence and variety of its viands, may compete with our best city hotels, and a weekly paper, that ably represents the character, wants and mental caliber of the county itself. I have seen few better country papers, for though small in size it covers a wide field of observation and thought.

The Kearsarge mine, which has been lying still for five years, is in this vicinity. New operations are in progress; and the Eclipse mine, on the Inyo side of the river, is now being worked with a 30-stamp mill on gold ore. The Inyo range on the east side of the valley has the appearance of one vast body of mineral, and must ere long develop a vast accumulation of wealth, such as cannot be found in California. In fact, the mineral wealth of this county is rapidly developing, and at no very distant day it will show itself second to none other.

Again taking the stage at four A. M., we have a ride of 40 miles further, and arrive about noon at Bishop Creek, a cluster of half a dozen houses, situated on the stream whose name it bears. Then a little ride of two miles more, and we are released of our wayfaring for the present. The new home is a picturesque little cottage, nestling close by the side of a prattling brook, born of the pure mountain crystal, overshadowed by beautiful trees that might well vie with the classic groves of Acadamus.

At another time I may give you some account of the natives, and the agricultural resources of the valley, but here for the present I rest, and here I work, to unfold great powers and purposes yet unknown.

FRANCIS H. McDUGALL.

Owen's Valley, May 24th, 1876.

Mineral Exhibition at the Centennial.

We take the following from a letter to the *Gold News* of June 8th: The mineral exhibition at the Centennial is well represented by four departments. First and best is the Lake Superior copper and silver. Next comes Chile, a very fine assortment of minerals and ores. Next comes Nevada and California, showing a magnificent selection of rich gold and silver ores, etc., the best portion being collected by Messrs. H. R. Whitehill and W. Frank Stewart, of Nevada. Next comes Mexico with some fine ore and mineral specimens, and one piece of silver and lead bullion, one quarter lead and the balance silver; weight, 4,002 ounces. It measures about 18 inches through. Next comes the Nevada mill, under the management of Hon. C. C. Stevenson. This is well represented, and the State of Nevada may well be proud of it. It has five stamps, runs well and is now working Belcher and Ophir rock. There is also Consolidated Virginia ore at the mill. Fine as these works are, however, people do not call there much, and to bring our mineral resources before the world properly could be better accomplished if Messrs. John Mackay and Col. Fair would bring here 20 tons or two carloads of bullion bars. This would take the premium and give credit to our State of Nevada; otherwise Lake Superior and Chile will have the best of it.

The Nevada quartz mill, and those mining tools from the Belcher mine are attracting a great deal of attention, and the general arrangements of this have been admirably carried out, reflecting great credit upon Hon. C. C. Stevenson and Mr. Smith, superintendent of the Belcher.

A METAL MORE FUSIBLE THAN TALLOW.—M. Lecoq de Boisbaudran, whose recent discovery of the new element gallium, and whose subsequent researches thereon we have from time to time noted, has recently, for the first time, succeeded in obtaining a grain and a half of the metal in a pure state. This has enabled him to determine the remarkable fact that gallium melts at 85.1 deg. Fah., so that it liquefies when held in the hand. When solid, the metal is hard and resistant, even to a few degrees below the melting point. It can be cut, and possesses a slight malleability. When fused, it adheres easily to glass, on which it forms a beautiful mirror, whiter than that produced by mercury. It oxidizes but very superficially when heated to redness in the air, and does not become volatile. The density at 59 deg. Fah. is 4.7, that of water at 39.2 deg. Fah. being 1. Exceeding mercury, which only becomes solid at -37.9 deg. Fah., there is no other element which liquefies at so low a temperature as gallium. Fusible alloy of one part lead, one part tin and one part bismuth, melts at 201 deg., and phosphorus at 111.5 deg. Wax and tallow have melting points respectively at 142 deg. and 92 deg. Fah.

Quicksilver.

The course of the quicksilver market has been very different this year from last, when it was subject to a number of disturbing influences. The greatest of these was the sudden and enormous increase in the production of California. It seemed doubtful for a time if the world's consumption was great enough to absorb all this surplus, except at very low prices; but, during the latter half of 1875, it was very clearly shown that between California and Nevada on the one hand, and China, Australia, Mexico and the South American republics on the other, an American production not exceeding 40,000 flasks, in addition to a Mexican production of 2,200 flasks, could be maintained without oversupplying the market. This would leave for consumers in the Atlantic ports the 48,000 flasks produced in Europe and the 2,000 received by Holland from Borneo.

This year the quicksilver market has been remarkably quiet, on the basis of £10 at London, 58c. to 59c., gold, at San Francisco, and 61c. to 62c., gold, in this market; yet there is probably as much reason for an unsettling of values this year as last. Official statistics thus far received from California show that the production in that State is again considerably increasing, and, in addition, we have intelligence of important discoveries of new deposits at Reno, Nevada. During the first six weeks of the current year there were exported from San Francisco 4,726 flasks, against 1,342 flasks exported during the same period last year. The bulk of this large shipment was sent to China, which seems to be capable of taking almost unlimited quantities at reasonable prices.

We have, however, no means of judging what may happen in that country in the course of the next few months, or what will be the result of the demonstration now making in that quarter by England, Russia and Germany. This may lead to a temporary blockade of the trade ports, causing a sudden check in the shipment of quicksilver to China; but were this event to occur, the increase in the silver product of Nevada, requiring increased quantities of quicksilver, may suffice to prevent a glut of that metal at San Francisco. In 1875 the Consolidated Virginia mining company reduced no less than 169,094 tons of silver ore, representing a value of \$17,209,733, and there was a large reserve of ore on hand at the beginning of this year, with a melting and assaying capacity of \$5,000,000 bullion per month. In Mexico, on the other hand, silver production is hampered by revolutionary disturbances, and less quicksilver will be required to supply the demands of that market than would be needed in times of peace.

The following are the official statistics of quicksilver exports from California, by sea, during the three years ended with 1875:

To	1872.	1873.	1874.	1875.
	Flasks.	Flasks.	Flasks.	Flasks.
New York.....	1,202	...	315	287
On shore.....	4,810	1,900	1,000	18,190
Mexico.....	5,038	3,761	4,104	5,757
South America.....	1,300	508	738	2,149
Australia.....	643	105	100	832
British Columbia.....	2	11	2	17
Other countries.....	103	74	311	1,728
	13,098	6,339	6,770	28,960

At 76½ each, lbs. 1,002,075 476,463 517,905 2,215,440

The following figures show the quicksilver movement in Great Britain:

QUICKSILVER MOVEMENT IN ENGLAND.

	1876.	1875.	Pounds.
Imp. from Jan. 4 to March 31.	1,251,682	1,104,522	979,580
Exports.....	149,421	208,892	676,080

Quantity retained..... 702,261 895,670 403,900

These English statistics, which are brought down to a very recent date, show that considerable quantities of quicksilver have moved through Great Britain, the bulk of which is received from Spain by the Rothschilds. From London, most of it finds its way back to the Continent. The average monthly distribution of quicksilver in Great Britain is usually set down at 3,500 flasks, or 267,750 lbs., for home use and export. For three months this would have amounted to 803,250 lbs., whereas it has been 1,251,682 lbs., showing that at prevailing low prices the distribution is largely on the increase in that part of the world. Last year fluctuations in prices were largely determined by momentary aspects of production. This year it seems to be exclusively a question of consumption. If China and Mexico are able to take as much this year as they did in 1875, even an increase of 10,000 flasks in the production of California is not likely to depress much, if any, the value of the metal, owing to the enormous expansion of the silver mining interest in Nevada.—*Iron Age*.

NEW MODE OF DECORATION.—The well known French earthenware manufacturer, M. Emile Collinet, has just discovered a new mode of decoration for private dwellings and public buildings. Instead of applying the decorated faience to the wall, he proposes enameling the stone itself, by putting up a light scaffolding and using the blowpipe instead of the oven. The advantages of the scheme are principally cheapness and durability. The experiments tried show that the process is less expensive than separate plates, and the decoration is calculated to last as long as the stone itself. The architect of the Louvre, M. Lafuel, has given his entire approbation to the process, and means to take the first opportunity of applying it under the inventor's superintendence.

SCIENTIFIC PROGRESS.

Micro-Photographs of Blood.

At the Massachusetts Institute of Technology, Dr. Cutter exhibited micro photographs of the blood of man and of some of the higher animals, taken by himself. His object was to ascertain what ground, if any, medical experts had for saying that they could distinguish the blood of a child from that of an adult, or that of a man from any other mammal. He had such photographs taken by the aid of a microscope, transferred to glass positives, and then thrown on a screen with the calcium light. The images can thus be measured either directly or by the eye, and any observer, not a microscopist, can determine for himself whether such discrimination is possible, as size is the only morphological element of the red blood corpuscle taken into account by such experts.

He exhibited the blood of man, rat, dog, pig, ox, deer, squirrel, sheep, horse, mouse, cat, rabbit, frog and trout—all taken with the same 1-50 objective, at a distance of twenty-six inches, and reduced upon the glass positives at the same distance from the camera.

Before showing the pictures he described the manner of taking them, as to articles employed, objectives, stand, slides, camera, and position of the various parts of the apparatus, and also the difficulties arising from the shaking of the building by the travel in the street, from focusing, and the arrangement of the light.

The averages of the measurements were as follows:

Man.....	1-3100	to 1-3200	of an inch.
Dog.....	1-3200	"	"
Squirrel.....	1-3600	"	"
Rat and Rabbit.....	1-3400	"	"
Deer.....	1-3900	"	"
Ox.....	1-3900	"	"
Pig.....	1-4028	"	"
Horse.....	1-4200	"	"
Sheep.....	1-5600	"	"

Other observers differ from the above measurements of Dr. Harriman, but always in a slight degree; and Dr. Woodward could not find any difference between those of man and the dog. Whether such small differences could be of any value in legal medicine he left for his audience to determine, showing, as he did, that in the same specimen the size varies considerably, and that, familiar as he was with the appearances, he could not at a glance distinguish them. He also exhibited the appearance presented by diseased blood in the various stages of consumption, showing very interesting and characteristic changes in the outlines, appearance and contents of the globules.

Animal Parasites.

Professor Van Beneden, of the University of Louvain, France, has recently written an interesting little work entitled "Animal Parasites and Messmates," in which he has contrived to compress a great deal of curious information regarding a subject much more extended than the reader not versed in modern progress of natural history would suppose. There is a fish, he tells us, called the *holothuria*, which is a living hoarding house for the *pierser*, an eel-like animal. The latter is lodged in the digestive tube of his companion, and, without any regard for the hospitality which he receives, seizes on his portion of all that enters. The angler or *beudroie* of the Mediterranean often harbors, in the bronchial sac, a kind of eel, which is abundantly able to take care of itself, but prefers to live a life of idleness and share its host's spoils. The eel is accompanied by the pilot fish, which does not, as is often reported, exist on the leavings of his larger companion, but on his own industry, and doubtless finds some advantage in piloting his neighbor.

Another remarkable fish, the *remora*, literally moors itself to the body of the shark, thus converting the latter into a vehicle, which carries him about without exertion on his part. When he becomes hungry he lets go, and hunts for prey wherever he may happen to be. The tenacity of the remora in attaching itself is taken advantage of by the fishermen of Mozambique channel, in order to capture turtle and large fish. They pass through the tail of the remora a ring to which a cord is attached, and then send it in pursuit of the first passer-by which they consider worthy to be caught. The fish holds on to its prey so firmly that it only remains to haul victim and captor in by the line.

There is a crab, of the family of *maidea*, which conceals itself in the substance of a polypoid; it is common in the Viti islands, in company with a gastropod mollusc, and both of them assume the exact color of the polypoid. This is a new kind of mimicry. Another crab appropriates a real anemone to form a living cloak to hide it from view, in order that it may spring out from its ambush to attack prey. Remarkable marine creatures are the *birgi*, a kind of crustacean, which grow very large, and conceal their abdomens no longer in a shell, but in the crevices of rocks. In the East Indies they remain on land and even climb trees. They have so much strength in their pinners that it is related that one, while stretched on the branch of a tree, "raised a goat by the ears." A family of isopods are rather dangerous messmates, it would seem, for they cut into the walls of their host's stomach and live like *Sybarites* on its contents.

The most interesting fixed messmates are the chirripedes, which cover the skin of whales,

which they never quit after once choosing its abode. Each whale lodges a peculiar species, so that the crustacean messmate is a true flag, which indicates in some respects the nationality. It would not be without interest for voyagers who are naturalists to study these living flags.

Among the mutualists may be mentioned the ticks, one generic species of which has 20 species, one of which lives on the dog, another on the cat, and another on the ox. Fishes harbor crustaceans instead of ticks, and these sometimes multiply so rapidly that they cover their hosts as though they took the place of scales. The cod gives lodging to a species of very beautiful shape, which in its turn affords a resting place for a still smaller organism. In the midst of the eggs of the lobster there lives an animal of extreme agility, which our author considers the most extraordinary being ever subjected to the eyes of a zoologist.

There is no organ which is sheltered from the invasion of parasites; even in man, *cysticerci* have been found in the interior of the lobes of the brain, in the eyeball, in the heart, and in the substance of the bones, as well as in the spinal marrow. Each kind of worm has also its favorite place; and if it has not the chance of getting there, in order to undergo its changes, it will perish rather than emigrate to a situation which is not suitable to it. One kind of worm inhibits the digestive passages; another occupies the fossa of the nose; a third, the liver or the kidneys. Each animal has its proper parasites, which can only live in animals, having affinity to their peculiar host. Thus the *ascaris mystax*, the guest of the domestic cat, lives in different species of *felis*, while the fox, so nearly resembling in appearance the wolf and the dog, never entertains the *tania serrata*, so common to the latter animal. The same host does not always harbor the same worms in different regions of the globe. Thus the large tapeworm of man, *bothriocephalus*, is found only in Russia, Poland and Switzerland; a small tapeworm, *tania nana*, is observed nowhere except in Abyssinia, and, strange to say, the natives consider their absence from the body a sign of ill-health; the *anchylostoma* is known only in the south of Europe and the north of Africa, the *filaria* of Medina in the east end west of Africa; and the *Bilharzia*, a terrible worm, has been found only in Egypt.

Alarm Against Suffocation by Gas.

Burglar alarms have come into extended use, in this country at least, and to them have been added fire alarms, to go off when a certain temperature is reached; and it has been suggested that a suitable alarm for coal gas from leaky stoves could be added, making use of the property that carbonic oxide possesses of precipitating palladium salts. Another modification has been invented by Aysel, for detecting the escape of street gas in a room. It possesses the advantage of simplicity, and its operations depend on a physical law, not a chemical one, namely, that the lighter a gas is the more rapidly it diffuses through a porous membrane.

The apparatus consists of a pear-shaped vessel covered with a porous membrane or unglazed earthen plate. This vessel has attached to it a U-shaped tube filled with mercury. One pole of the battery dips into the mercury, the other terminates just above the surface of the mercury in the open end of the tube. If this apparatus is placed in a room where coal gas is escaping, the gas enters through the porous plate more rapidly than the air can escape; a certain pressure is produced, which causes the mercury to rise in the open leg and complete the circuit, thus giving the alarm. It is said that a comparatively small amount of gas in a room will set the apparatus in motion. A similar apparatus with the opposite arrangement of the terminating wires could be employed for detecting a large escape of carbonic acid from any source, for this gas is so heavy as to at once produce a partial vacuum in the pear-shaped vessel, and, of course, a fall of mercury in the open leg. The amount of carbonic acid requisite to vitiate an atmosphere is, however, so small that it would probably be without effect on this instrument. There may be other cases where the pressure of gases much heavier or lighter than air could be detected more quickly by this than by the ordinary methods, as in coal mines and wells; while an advantage is that signals may be automatically conveyed to any desired distance. This seems, at least, a promising field for inventive genius and research.—*Scientific American*.

Germs.

In an interesting article on spontaneous generation, by Rev. W. H. Dallinger, published in the *Popular Science Review*, he shows that the germs of bacteria and monads may be so infinitesimal as not to be revealed by the microscope, and only by means of physical processes such as were instituted by Professor Tyndall, who "has presented us with a physical demonstration of the existence of immeasurably minute molecules of matter, utterly beyond the reach of the most powerful combination of lenses yet constructed, which are the indispensable precursors of bacteria in sterilized infusions. In short, he has opened up a new and exact method which must lead to a scientific determination of the existence and nature of the bacteria germs. The particles which Tyndall was enabled to detect by passing a beam of light through them Mr. Dallinger was unable to detect with an exquisite one-fiftieth objective, employed with a new and delicate mode of illumination for high powers and worked up to 15,000 diameters. After demolishing Dr. Bee-

man, he thus sums up what he regards as the facts concerning the theory of spontaneous generation: (1) Dr. Tyndall has proved, in connection with a host of others, but in a more definite and precise manner, that in filtered infusions five minutes' boiling does kill every form of bacteria; (2) he has further shown that they are propagated by demonstrable germs only in such infusions; and (3) this fact removes the probability of their spontaneous generation to an almost infinite distance. He says:

"As to the development of bacteria in infusions charged with solid matter, precise experiment of a sufficiently comprehensive character has yet to be made on them in relation to the demonstrated germs. Meantime, shall we accept 'spontaneous generation' on such ground as its strongest advocate has now to offer, and ignore the vast chain of facts, copiously attested and controlled, which are in perfect harmony with the known laws of the entire organic world? This, and nothing less than this, is what Dr. Bastian inculcates and demands."

MECHANICAL PROGRESS.

Accurate Measurements.

How much of good workmanship depends upon accurate measurement. The skilled mechanic who never fails of a fit knows that his strength lies in his rule or his calipers and his knowledge and care in using them. But how many have thought how accurate a measurement must be to be true to the perfection of mechanism. We find by our English exchanges that at the last Kensington exhibition of scientific and mechanical apparatus there was a discussion on the value of accurate measurements, from which we draw several interesting points:

Dr. C. William Siemens, in his opening address, dwelt upon the value of accurate measurement as the most important aid to discovery. To know was to measure. The Egyptians used the power of steam to work such pretended miracles as that of the spontaneous opening of the doors of the temple whenever the burnt offering was accepted by the gods—or, as the moderns would put it, whenever the steam generated by combustion was sufficient to produce steam in the hollow body of the altar, and thus force water into buckets whose increasing weight caused the gates to open. Unfortunately for them, the Academia del Cimento of Florence had not yet presented the world with the thermometer, nor had Torricelli shown how to measure elastic pressure; or there would have been, at all events, a probability of their applying the power of steam for transporting the materials and raising the water in their elaborate works of irrigation. After speaking of several other kinds of measurement, the President passed to the measurement of heat. The principal instrument here employed is, he remarked, the thermometer. He would not speak of the different scales adapted by Reaumur, Celsius and Fahrenheit, which were based upon no natural law nor zero points in nature, and were, therefore, equally objectionable upon theoretical grounds. Would it not be possible to substitute for these a natural thermometric scale? Was it not possible to adopt one commencing from the absolute zero, of the possible existence of which we have many irrefutable proofs, though we may never be able to reach it by actual experiment?

Sir J. Whitworth read a paper on linear measurement, in which he compared line with end measure to the disadvantage of the former mode of ascertaining length. In illustration of the advance made in accurate measurement, he said that 50 years ago the thousands of spindles in a cotton factory had each to be separately fitted into the holster in which it worked. At the present time all these spindles are made to gauge and are interchangeable. The foundation of accuracy in measurement is, he said, the production of the true plane, and he exhibited planes such as are produced in the workshops of his company. The millionth measuring machine Sir J. Whitworth did not exhibit, but he performed a sufficiently striking experiment with one of his gauges. He passed a pencil between the two points. Then he advanced one of these two points a little nearer to the other, just one twenty-thousandth of an inch. The breadth of the pencil was thus ascertained within one twenty-thousandth of an inch.

In the course of the discussion which followed, M. Treaca said they wanted to ascertain thickness equal to one-thirtieth of the breadth of a cobweb.

Mr. Chisholm, warden of the standards, recommended linear measurement, on the authority of the careful investigations of the commissioners of the standards, and by other arguments, and the President thought that linear measurement was applicable to long distances, and end measurements to small differences and small pieces.

Sir J. Whitworth, in his reply, said that the commissioners of the standards, men of great scientific attainments, had not the experience of the workshop (they did not know how to use their hands), and in proof of this, he said they represented the standard-yard by a piece of bronze of a certain length at a temperature of

62 deg. But the temperature of the human body was such that you could not touch anything at 62 deg. without raising its temperature and so causing expansion, and he himself proposed that the standards should be made and kept in a room at a uniform temperature of 85 degrees.

Mr. Merrifield, F. R. S., spoke upon solid measurement, explaining, among other instruments, Amies's planimeter, and several rough-and-ready means of finding the contents of casks; etc., for fiscal purposes. He then described a more accurate means of performing those tests—Dr. Werner Siemens's alcoholometer, which has been in use in Russia for four or five years, and is said to have added 25 per cent. to the receipts of the Russian government from the duty upon spirits made in the country. All the spirit made in a distillery is conducted from the condenser by pipes, which are exposed throughout, so as not to be capable of illicit tapping, to this instrument; and, in the passing through, the total amount of spirit and also the amount of alcohol in the spirit are recorded by counters, which may be inspected, from month to month, or oftener. The instrument is enclosed in a strong iron case.

In the afternoon, Sir William Thomson gave a historical account of electric measurement. The manuscripts of Cavendish, he said, would be found of the greatest interest, a whole branch of electric measurement, the measurement of electro-static capacity, being worked at in them. The manuscript had been preserved in the family of the Duke of Devonshire, and had now been placed in the Cavendish laboratory at Cambridge, under the charge of Professor Clerk Maxwell, by whom they would be edited. Electrical measurement was now so advanced that there was no reason why Leyden jars should not be labeled, as a matter of course, "the capacity of this jar is so many centimeters."

Subterranean Telegraph Joints.

At a meeting of the Society of Telegraph Engineers, a paper by Willoughby Smith was read on the "Formation of Joints in Gutta-percha Covered Wire for Subterranean and other Telegraph Lines." The author has given careful attention to the subject, and had at length succeeded in inventing what he had no doubt would prove a simple, cheap and efficient mode of dealing with one of the practical difficulties of subterranean telegraphy. The new joint is formed by removing the coatings from the two ends to be united and joining the cleaned wires by what is technically known as the "bell hanger's twist." No solder is necessary. The twist is then wormed slightly and covered with a rough coating of insulating compound, somewhat thicker than the original diameter of the wire. The joint while warm is placed in the lower half of a small wooden block about three inches long and one inch wide, fitted internally with a groove for the wire, widening in the middle into a notch about one and a half inches in length for the reception of the compound covered joint. While the compound is yet warm the upper half of the mold—in shape corresponding exactly with the lower one—is placed on the top, and, by means of a clamp, screwed down until the two wooden surfaces are pressed firmly together. While in this position they are permanently fixed by half a dozen ordinary brass screws, and the compound having hardened, the clamp is removed and the joint complete. The cavity in the interior of the block in which the copper ends meet being completely filled with compound, the insulation is all that could be desired, numerous experiments carried out by the author having satisfactorily tested the electrical qualities of the arrangement. The cost is thus reduced to a very low figure, and by means of the wooden covering all danger of "leakage" or separation of the wires through bending is obviated. The joint was not of course applicable except in cases of emergency, to sub-marine cables, but as far as the author could judge was all that could be desired for the purposes for which it had been designed.

The First Railway in China.

A little railway is being laid down between Shanghai and Woosung, a town at the junction of the river Hwang-poo, (on which Shanghai is situated) with the Yangtze. The distance is only nine miles, but the great object is to establish a railway of some kind on Chinese soil, in order to show the people what it is like. The land was quietly bought up by a few foreign merchants, the roadway levelled, and a company subsequently formed to carry out the undertaking. A large portion of the required capital was subscribed in England, and the remainder in Shanghai. The mandarin have been all along jealous of the proceedings of the company, and are doing their best to embarrass it, but the rest are perfectly well disposed. They often come to look at it, and only yesterday (says a Shanghai correspondent of the *Times*, writing on March 23d), several very respectably dressed Chiese who had come for the purpose were invited to ride in the ballast-trucks. They were a little timid at first, but eventually accepted the offer and were delighted with the experience. The engine which is being used is only of two or three horse power, and hardly bigger than a good sized Newfoundland dog. The Chinese are employing an English engineer, Mr. Tyeck, and English machinery, in an experimental opening up of the coal mines of Kelung, North Formosa.

Mining Share Market.

The whole market during the past week has been rather on the decline. Even the omnipotent Con. Virginia has moved on the downward path. Everybody on California street makes a long face and only a few fortunate shorts are looking healthy. Hale & Norcross, which made such a good start, dropped again and all we can learn by the single one is a long question: What is the matter with Consolidated? Has the bottom been reached? Or what? But there is no answer to that question from the managers of the mine, and as it is with mining stocks, as with a new fashion—when the leaders drop it, the followers do the same, we will most likely see some very rough business going in the boards for the next week to come.

One of the best known members of the old board, Mr. Jas. H. Latham, died last week on the voyage to Europe. In respect to his memory the board was closed on Monday afternoon.

Rock Drilling.

The following table is from Mr. E. C. Burr, Superintendent of the Mariposa land and mining company, and has evidently been carefully prepared. We are ready to print reliable statistical matter which is of general interest.

Machine Drilling in River Tunnel, Mariposa Estate, From April 24th to May 20th, 1876.

the 1700-ft level getting along well. The north drift at the 1400-ft level is advancing at a very good rate in favorable material.

NORTH CARBON.—The new compartment to the shaft being completed gives a first-rate, well timbered, three-compartment working shaft from the surface down to the tunnel level. The new hoisting works will be able to start up in a day or two.

TAHOE.—The combination shaft being sunk on the line between this and the Lady Bryan claims by both companies, is being sunk at a lively rate. It is very favorably located and when deep enough will be made connect by drift with the 330-ft level of the Lady Bryan mine.

HALE & NORCROSS.—The new pumping machinery arrangements are being pushed forward to completion with the characteristic energy of the management. The new boilers are in place, the building over them completed and in the main incline the tanks and bob pits for the pumps are being cut out.

ELCZER.—Daily yield, 400 tons, the old ore producing levels holding out pretty well yet, although the ore is not of very high grade. It pays expenses pretty well, however.

UTAH.—The lift-pump just put in at the 650-ft level is working splendidly, and a drift is now being run around the shaft to the tank, in order to run all the water flowing from the level and above to the tank, to ascertain if it is not practicable to sink the shaft deeper hereafter without any pump below this level.

UNION CONSOLIDATED.—The face of the north drift at the 1300-ft level continues in very favorable ledge material, consisting of porphyry, clay and low grade quartz. **BALTIMORE AND AME LOAN FLAT.**—The face of the main drift at the 1250-ft level is in porphyry, clay and quartz, and the drift at the 1030-ft level is in the same encouraging material.

DARTON.—Sinking of the main shaft deeper proceeds at a satisfactory rate. The drifts north and south at the 500-ft level are getting along finely.

FLORIDA.—Main drift at the 400-ft level continues impeded by an overplus of water, but the work of clearing out and re timbering is being pushed ahead to completion.

SILVER HILL.—The strong flow of water in the incline still continues. Rock at the bottom rather hard and sinking progresses necessarily slow.

LADY WASHINGTON.—Bottom of the shaft still continues in the same very favorable Comstock vein matter and the shaft is making the usual excellent progress.

SILVER NEVADA.—Good work is being done in the various drifts at the 1000, 1250 and 1500-ft levels, with no new ore developments to note since last report.

WELLS-FARGO.—Work driving ahead vigorously with three shifts of men. Face of drift in very promising looking vein matter.

TWIN PEAKS.—The fine white Comstock ore development in the shaft of this mine continues its excellent showing.

LADY BRYAN.—Very good progress is being made with the excavations and stone work for the new machinery.

CONSOLIDATED VIRGINIA.—Daily yield, 550 tons, from the regular producing levels. The drift east from the 1600-ft level to connect with the C. & O. shaft is advancing well, and the drift west from the shaft to meet it is progressing at a still more rapid rate, owing to better air and working facilities. The great heat in the drift north at the 1700-ft level impedes the progress considerably at that point. Work on the new steam mill and the new pen or amalgamating mill is driving ahead energetically, and the foundation for the condenser of the pumping engines is nearly completed. The usual monthly dividend of \$2 per share was declared day before yesterday.

CALIFORNIA.—Daily yield, 350 tons of ore. The extraction of the ore is going on very actively, but just commenced, and each month's yield of bullion continues to surpass the other in regular progression highly gratifying to stockholders. The usual monthly dividend of \$2 per share is declared to day, aggregating \$1,030,000. The lateral drift at the 1400-ft level reached its connection with the Ophir mine last Monday, giving valuable air circulation. The strong flow of water in the C. & O. shaft is now impeding progress, about 15 or 16 feet per week being the regular progress. The drift to connect with this shaft at the 1500-ft level is progressing at a very lively rate from both ends.

IMPERIAL.—North winze below the 2000-ft level, near the Alpha, down 62 feet, with very excellent ore the full size of the winze, which assays from \$100 to \$1,000 per ton. The south winze, near the Coudeance north level, is down 23 feet and will shortly connect with the north drift on the 1940-ft level of the Yellow Jacket mine. The bottom is in easy working ledge material.

JUSTICE.—The ore stops at the 600-ft level, as well as the upraise from that level, are looking and yielding well, and showing improvement as further opened and developed. At the 800-ft level the face of the south drift is also showing well, and is evidently fast nearing its intersection with the ore body from the 600-ft level. The flow of water continues strong, with no abatement, but is handled with ease, the pumping and other machinery operating splendidly.

CROWN POINT.—Excellent progress continues to be made with the south drift at the 1700-ft level, and the east cross-cut at the 1600-ft level, with no new features to report at any point.

MAZON.—Sinking the shaft for another level is actively resumed and making excellent headway. The new pump is working well, handling the water to very good advantage.

ORILLAB-POTOSI.—Daily yield, 115 tons, giving an average assay of \$31 from car samples. The bullion production for May footed up to \$29,224.40. The drift east at the 1350-ft level having connected with the Julia shaft, air is being conveyed advantageously, circulation of air is secured. Sinking the main incline proceeds at the usual satisfactory rate, and the new combination shaft is making excellent progress.

JULIA.—At the 1500-ft level the main southwest drift is advancing slowly, owing to the intense heat, and is in a very favorable formation of clay and quartz. The rest of the main west drift at the 1600-ft level is now in soft, wet porphyry, with small streaks of quartz and clay.

OVERMAN.—The daily yield is now about 25 tons, coming from the 900-ft level. The ore breasts at that point hold out well, and give good promise for the future. A plunger pump is being put in at the 1200-ft station. The pit for a tank at that point is completed, and sinking the shaft deeper will be resumed in a day or two.

CALIFORNIA.—A heavy flow of water was tapped last week in the shaft, which increased so fast that the pump was overpowered, and sinking had to be suspended. It rose to the height of 60 feet, but the pump has got the best of the situation.

ORILLAB.—Daily yield, 185 tons. The ore sections are showing improvement at the 1500 and 1600 ft levels, and the north drift at the 1600-ft level is making very good advancement toward the Mexican line. The cross-cut from the north drift at the 1100-ft level is fast nearing its connection with the upraise from the 1300-ft level. Sinking and raising for the main incline connection between the 1600 and 1700-ft level progresses at a very favorable rate, and the work in the mine generally is getting along finely.

SUTRO TUNNEL.—Total length of tunnel to day, 13,348 feet. Water still on the increase, but any sudden and disastrous flow is carefully guarded against by keeping ahead some distance. Good little streaks of low grade ore are quite frequently cut through by the face of the header.

COMMONWEALTH.—The upraise from the main tunnel or adit level has at last been brought to a surface. A splendid and much needed supply of pure air thus secured. The good ore resources developed by this winze will be made available at the earliest opportunity.

MOORE.—The water encountered proving to be a little too much to manage with present facilities, sinking had to be suspended until the proper pumping and hoisting machinery can be procured and erected. This

is contracted for and will be brought to bear in the case as soon as possible.

MEXICAN.—The face of the north drift at the 1465-ft level is in very favorable looking ledge matter, being in the wall of the ore vein. Cross-cutting will be done when the proper point is arrived at. Sinking the winze below this level at the west side is commenced.

ALTA.—The new surface machinery is being placed in position as fast as possible, and the work is being done in a very substantial, workmanlike manner. When completed, the Alta hoisting works will compare favorably with the best in the Comstock lode.

GOLD & CURRY.—Good progress continues to be made re timbering the double winze or incline, and the bob and tank pits for the new pumping machinery are being got ready as fast as possible. Hot air impedes progress at the lowest levels considerably.

SAVAOE.—Lively work is being done getting the surface machinery arrangements well under way. The hoisting and tanks in the shaft are already completed, and the pump will be started to running at the earliest practicable time.

BUCKEYE.—Both drifts north and south are pushing ahead. South drift in good ore indications, and a raise will soon be commenced from it to connect with the winze being sunk from the level above. Water decreasing.

COMMONWEALTH.—Excellent work being done sinking the shaft, the rock working favorably and showing very good ore indications. The face of the tunnel is in highly encouraging material, showing and promising well.

EUROPA.—Sinking the shaft goes steadily ahead as usual. The material at the bottom works easily and favorably. Some little increase of water has been encountered, but it has subsided again to the regular quantity.

DERBY.—Rock at the bottom of the shaft working favorably, allowing of good progress. The frame for the hoisting works building is being got ready. The building will be substantial and of good size for the purpose.

PERSPECT.—Nineteen more feet in depth has been added to the shaft since last week's report, making it 302 feet deep in all. The steam pump keeps the water out.

NORTH CON. VIRGINIA.—Some increase of water, with rock about the same as last week—rather hard. Are hurrying up work on the foundations for the new pumping machinery, and making good progress.

WEST BELCHER.—Work progressing well in both west and northwest drifts. Are now busy putting up an ore dump. Shall commence the extraction and milling of ore as soon as the dump is completed.

WARD.—New machinery nearly ready to start up. Meanwhile the grading and stone work for the surface buildings is being pushed forward actively and the sinking of the shaft progresses as usual.

ORIGINAL GOLD HILL.—Sinking deeper for another level is resumed. Shall drift for the south ore body at 100 feet deeper than present bottom of shaft, which will open up a large amount of good pay ore.

ALABAMA.—Sinking the new three-compartment shaft was suspended for a few days in order to make a road and bring in the requisite timbers. This is completed and sinking goes on as before.

PROTON.—The winze station in the main north drift is completed, and sinking the winze is actively commenced under the most favorable auspices. Rock works easy and no water to trouble.

VIVIAN.—The usual quantity of good milling ore continues from the old stopes, and some very fair ore is being produced from the 120-ft level. No more trouble from water in the incline.

BALTIMORE CONSOLIDATED.—Excellent stringers of favorable looking quartz are being cut through this week by the drift, and better headway is being made than heretofore, the rock being softer.

NEVADA.—Drift pushing steadily ahead in quartz and porphyry. Expect to reach main ore chimney before long, judging from present indications.

GLASGOW.—The heavy flow of water encountered is being drained by the sinking of the combination shaft to the level of Glasgow.

COLUMBIA.—As soon as the enlargement of the shaft is completed, which will be very shortly, sinking deeper will be resumed.

ROUGH & READY.—The financial and legal troubles are being settled, and sinking will be resumed as soon as deemed expedient.

ROCK ISLAND.—South drift at 650-ft level has a fine showing of very favorable quartz in its face, some streaks of which assay well. The west drift at the 850-ft level also shows considerable improvement, and the north drift at this level is making good progress in fine looking quartz.

BEST & BELCHER.—Repairs to the double incline winze being forward at as lively a rate as practicable, and when the Gould & Curry pumping arrangements are completed and at work, the development of this mine will be proceeded with.

KOSUTHA.—Work going ahead lively at all points, the water being drained but no new features of interest to report this time.

ANTICREBOCKE.—Bottom of shaft in easy working ledge material, with little water to interfere with good progress being made in sinking.

SOUTHERN CON. VIRGINIA.—The ledge is showing finely, giving excellent assays and widens as it is followed north, with well defined walls.

MINT.—Shaft down 1,113 feet and bottom now in hard country rock. No increase of water. Machinery working well.

LEVATHAN.—Rock in face of drift somewhat softer and more favorable than last week. Drift in 133 feet. SEMANOR CON. VIRGINIA.—Sinking at present in very encouraging vein material and getting along finely.

MORNING STAR.—Making the usual good progress in sinking the shaft. Nothing new to report.

NIAGARA.—Main incline shaft down 329 feet, with bottom in soft and favorable vein matter.

DANEY.—Sinking the shaft is resumed, the pump having got the best of the water.

DEVON.—Sinking the shaft is resumed, the new steam hoisting works operating well.

EAST OVERMAN.—The quartz in the bottom of the shaft shows well and gives good assays.

PHIL SHERIDAN.—Shaft down 178 feet with the bottom in favorable working material.

MONUMENTAL.—Shaft 183 feet deep, with bottom in hard rock but blasting well.

NEW YORK CONSOLIDATED.—Nothing new to report. Work going ahead as usual.

ANOTHER GAS MACHINE.—An apparatus for the manufacture and utilization of combustible gases has been patented in England. In this invention bituminous coal is placed in retort and subjected to distillation. The rich hydrocarbons are eliminated therefrom in the form of gas, but when the stage of distillation is reached at which the sulphurous and phosphoretted gases are disengaged from the coal the gaseous products of the retort are diverted from the previous and purer product, and are passed into water or carried to the furnace, in order to aid by their combustion the heating of the retort. The result is a comparatively pure hydrocarbon gas and a coke practically free from sulphur, phosphorus, etc. From the purifiers the gas passes to the gasometer. From the gasometer the gas is passed to a retort filled with broken fire brick; as the hydrogen is separated from the carbon it assumes the volume peculiar to the gas.

Pig Iron Trade of San Francisco.

The quantity of Iron used on this coast annually, whether in the shape of Pig Iron, Bar and Bundle, or manufactured into Hardware, etc., cannot be less than 60,000 tons, worth manufactured at least \$3,000,000. In a manufactured state it is worth at least \$10,000,000 a year. It is, therefore, one of the most important articles of merchandise that is dealt with in this port. And when we say that during the past ten years our people have paid out seventy millions of dollars, the greater part of which has gone into the pockets of foreign and Eastern merchants and manufacturers, it will be allowed that the development of the iron resources of this coast is at least worth an effort. In this regard a statement of the imports and consumption of Pig Iron for the past few years is not without interest, and we here present one to our readers.

The consumption of Pig Iron on this coast has increased in an irregular way for the past seven or eight years, and was last year double what it was in 1870. The greatest previous consumption was in 1874, and the next in 1871, when 12,509 tons were worked up by our foundries. The following table gives imports, consumption and stock at the close of every year since 1869, inclusive of that year:

	Imports.	Consumption.	Stock over.
1869.....	Tons 13,820	8,674	12,663
1870.....	9,323	9,282	12,647
1871.....	5,499	12,509	5,537
1872.....	13,168	10,234	8,571
1873.....	8,337	9,122	7,786
1874.....	8,414	14,816	1,394
1875.....	25,584	17,718	12,260

It will from this be seen that the importations of 1869, which were a third greater than those of 1868, were not kept up for the two following years, but that they fell off, until in 1871 they were less than one-half what they had been two years before. All this while, however, the consumption continued to increase, till in 1871 it was 12,509 tons—fifty per cent. greater than in 1870. In 1872 the importations rose again to the figures of 1870, while the consumption diminished, as it did also in the following year. These were two medium years for the iron foundries, and the importations again fell off, to increase a little in 1874, and last year to reach 25,584 tons, the greatest ever known in the State, and more than double that of any previous year since 1868. This was caused by the activity of the foundries last year and the increase in consumption, which was far and ahead that of any previous year in the history of the State.

Prices have varied much during the past seven years. In 1869 they ranged from \$30 to \$45 per ton—nearly the same range as last year, which was also like 1870, a year of large importations. The following year the price was low, declining towards the close to \$29.50 and \$30.00—subsequently recovering to \$34.50 and \$35.00, at which it closed. During 1871 it ranged from \$32.50 to \$34.00 for the greater part of the year, advancing to \$50 and \$55 towards the close, as stocks had run very low. The next year was a high one in the Pig Iron market, the price running up to \$75 and \$80 in the Summer, but declining towards December to the opening prices of January. In 1873 high prices also prevailed, but towards the close there was a decline, which reached its lowest point in June, 1874. From this to the close there was an advance, but the past year has witnessed a very decided decline, and now prices are on the basis of what they were seven years ago. The market for White Pig Iron has followed nearly the same course. The following tables give the prices monthly for the past six years:

Scotch Soft.			—1871—			—1872—		
January.....	\$33 @ \$34	\$34 @	—	\$52 @	—	—	—	—
February.....	33 @ 34	34 @	—	45 @	\$57	—	—	—
March.....	32 @ 34	33 @ \$34	—	56 @	60	—	—	—
April.....	31 @ 32	32 @ 34	—	70 @	75	—	—	—
May.....	30 @ 31	32 @	—	70 @	80	—	—	—

Since the beginning of the present year importations have been heavy, consumption light, and prices low, but a good demand is anticipated. Imports for the first four months of the past two years compare as follows:

As the resumption of work by the foundries has been slow this year, and as there are large quantities on the way, no very great advance on present rates may be expected during the balance of the season.

The consumption of 1876 will doubtless be equal to that of the last, as there may be anticipated a vigorous resumption of work and its con-

tinuance throughout the Fall till towards the close of the year. Of this Oregon will probably supply 1200 tons, and this is all that may be expected from Pacific Coast sources for some time. The Iron of our sister State is of the very best quality, and has always commanded a ready sale in our markets, and the enterprise which has mined it and shipped it to this city might in this State be very well imitated. We possess illimitable Iron resources, and it argues a great lack of industrial vigor that we have allowed them to go undeveloped so long. It also argues a lack of good sense, for the manufacture would undoubtedly pay, while our people neglect it, at the same time that they run wildly after every wildcat gold and silver mine from this to the Missouri.

We have all the Iron ore that we will ever want, timber fitted for making Charcoal adjacent to the ore beds, a consumption yearly in Castings, Railroad Iron, Manufactured Iron and Hardware of 60,000 tons—one, too, constantly increasing—we need associated capital, enterprise and skill. When we have utilized these in the development of our Iron resources, we shall have added largely and enduringly to our riches. A Birmingham or a Sheffield on this coast would find customers from Behring's Straits to Terra del Fuego, and from Panama to the Cape of Storms. —S. F. Journal of Commerce.

Odd Moments in the Shop.

There is probably no more important question one can ask the young man in the shop, than "What do you do with your odd moments?" Upon the way in which his spare time is employed depends, in great degree, a man's success in life. We have been in shops in the country where an idle afternoon was spent in playing checkers or "loading," and where the only reading done was of newspaper stories of the cheapest kind. Young men who fall into the habit of wasting the time in the shop during which they cannot be at work, are neglecting their opportunities. Sometimes athletic sports take up all the moments that can be spared from labor. It is rare, however, to see a young man busy at such times with anything which can in any way be useful to him. We know of one young man, at every opportunity, studied the engine of the establishment, and used it the first chapter of a course in mechanical engineering. Three books on the subject were bought and kept at hand, so that at any time they could be taken up. In a short time he was promoted into the engineer's department—as wiper, if we remember rightly. This gave him more time in working hours, which was devoted to the study of the engine, the theory of steam, valve gears, etc. As wages were increased more books were bought, and in this way the young man obtained a superior knowledge of the trade, which in the end was a source of great revenue to him. In the shop is emphatically the place to study the trade at which one is at work. Leisure moments, if improved, will often enable one to obtain a vast amount of practical knowledge. Out of the shop there are thousand things to distract the attention, the tools are not at hand, and a good share of courage is needed to hold the attention down to work. In the shop it is not nearly so hard. Conveniences are at hand, and everything is favorable to the acquisition of knowledge. It will be found a general rule that men are quite willing to instruct those who seek after knowledge, and in the shop the older and more experienced are often very glad to take pains with the younger ones, if they only show an interest in improving. Unfortunately, there are too few young men who care much for extra instruction. They only wish for so much knowledge as will carry them through the ordinary journey work, and do not aspire to become superior workmen.—Iron Age.

PRODUCTION OF SILVER IN THE WHOLE WORLD.—According to recent statistics the production of silver in the whole world in 1800 was \$35,000,000, which rose in 1850 to \$42,500,000, in 1854 to \$47,500,000, and in 1865 to about \$62,500,000. The production of this precious metal during the year 1873 is subdivided as follows: England and its colonies, \$10,000,000; Norway, Sweden and Denmark, \$250,000; Russia, \$500,000; Austria, \$1,620,000; Germany, \$3,000,000; France, \$2,000,000; Spain, \$2,000,000; Sardinia, \$500,000; Mexico, \$20,000,000; Central and South America, \$8,000,000; Canada, \$900,000; the United States, \$36,500,000, which gives a total of \$85,250,000. Including the year 1873, it is estimated that the total production of silver, since the discovery of the new world by Christopher Columbus, has been \$715,000,000, the largest source of accession, during late years, being due to the Nevada mines.—Scientific American.

IRON SHEETS THINNER THAN PAPER.—We have heard of iron as thin as paper, but have just had a packet of specimen iron sheets brought to our office, not half as thick as the sheet this is printed on. This sheet is 0.004-inch in thickness; the iron sheets we have received are 0.0015-inch thick, or only three-eighths the thickness of the paper. At the same time the iron sheets are so tough as to be torn with difficulty, and so flexible as to bend with almost the facility of ordinary printing paper. These wonderful specimens of iron were made from the rough pig up to the rolled sheets by our neighbors, the Pearson and Knowles iron company, whose skillful manager, Mr. Hooper, has discovered a means of rolling these infinitesimally thin sheets in numbers without their sticking together.—Warrington (England) Guardian.

USEFUL INFORMATION.

Hanging Shafting.

Mr. R. James Abernathy, of Moline, Ill., gives the following practical hints on putting up shafting: A line of shafting should be perfectly straight, with no twist whatever in the bearings, and more particularly so if it be a rapidly moving shaft. A very quick moving shaft with the least possible twist causes unnecessary friction, and makes a wonderful difference in the power required to drive it; and in slow moving shafts this difference is proportionately great.

The first or main line of shafting ought to be squared with the building, and all other lines, whether parallel to or at right angles, should be taken from that. Parallel lines can generally be carried over by correct measurement from extreme points, and this is really the most correct way of getting counter lines.

For a line running at right angles, first establish a center point on the line already down, then two other points at convenient and equal distances on each side of the center point; then procure a long sweep, and, from the points made, describe two short arcs, and where these two arcs cross or cut each other, make a point, and from the center point already made on the main line draw a line through the point last made. If done very correctly, it will form an exact right angle or square line. This, in geometry, is called erecting or raising a perpendicular, and it is among the first lessons taught in that branch of mathematics. To the practical mechanic it frequently becomes useful in many ways. Lines of shafting running at right angles are always connected by bevel or miter wheels, and in gearing these together it is important to have the centers very exact, as the least variation will make the teeth bind, causing them not only to run hard but to make much noise.

Pitch lines should run together, or as nearly so as possible. In this respect, however, millwrights are frequently troubled on account of wheels not matching properly. This is the fault of the pattern maker. In such cases the millwright must exercise his judgment in setting them together so as to run freely and easily.

In addition to being perfectly straight, all lying or hanging shafting must be perfectly level, and all upright shafts must be exactly plumb or perpendicular. By following these few simple directions there need never be any bad working shafting.—*Iron Age*.

How to Paper a Wall.

The paper, first of all, is to be trimmed on one edge; then get the height of your ceiling, cutting the bolts into pieces of proper length, and matching the figure carefully.

For a paste clear corn starch is the best, made precisely as you make for starching clothes. It is well to use a small quantity of carbolic acid in it, as a protection against vermin. A thin paste of wheat, or better, rye flour, is, however, very good for anything except the most delicate papers. The wall should be smooth, and if very smoky, or greasy in spots, it should be washed with weak lye or soap suds.

Lay your trimmed and cut paper, face down, on a long table or smooth board; with a brush—an old whitewash brush is good—spread the paste evenly over the upper piece; do not put more than just a coating on; then take hold of the lower end of the piece and fold it loosely over, part way up, then lift the piece up and fix it carefully in place, smoothing it down with a towel or cloth. Never mind a few wrinkles, they will all disappear as the paper dries. Put the next piece on the same way, matching nicely, and overlapping the trimmed edge on to the untrimmed edge of the first. It is much easier to have an assistant to care for the lower part of the pieces as you put them on. Skip spaces over windows and doors, and fill them up when the rest is done; then put up the border, cutting in convenient lengths for handling.

A word on the style of papers. Avoid glaring contrasts in colors, and large staring patterns, as out of taste and tiresome to the eye. Choose rather neutral tints, and colors that harmonize and blend agreeably together and with the general tone of your carpets and furniture. Even with a bare floor and plain wooden chairs, the effect of a soft tinted paper gives a vastly different impression than if the wall is disfigured with glaring figures and contrasting colors. If your ceilings are low, lighten the appearance by a figure which runs perpendicularly through the paper.—*Western Farm Journal*.

Classification of Nails.

The origin of the terms "six-penny," "ten-penny," etc., as applied to nails, though not commonly known, is involved in no mystery whatever. Nails have been made a certain number of pounds to the 1,000 for many years, and are still reckoned in that way in England, a 10d being 1,000 nails to ten pounds, and 6d, being 1,000 to six pounds, a 20 weighing 20 pounds to the 1,000 and having just one-half the number of nails to the 10 pounds of the 10d, and in ordering the buyer calls for the three-pound, six-pound or ten-pound variety, etc., until by the Englishmen's abbreviation of pnn for pound the abbreviation has been made to stand for penny instead of pound, as

originally intended; and when it comes to less than one pound to the 1,000, such as tacks, brads, etc., they are reckoned six-ounce, eight-ounce, 12-ounce, etc., and the manufacturer who would make less than 1,000 nails to 10 pounds for a 10d. nail, would be looked upon as a cheat, as in former times the difference in the cost of the manufacture of one pound of the small nails over the larger sizes was much greater than now. As nails are now made and sold, the dealer only asks for the size needed, by the usual designation, and the fact that there are now but about two-thirds of the number of nails formerly called for in the pound does not lessen the value.

STAINING GROWING WOOD.—Professor Stebbins, in a letter to one of the photographic journals, declares that, ere long, we shall be able to have all our furniture—even articles of common deal—of such a beautiful color as to throw out of fashion mahogany and other foreign woods. A Freuchman has discovered a new method of compelling the tree to color itself. He operates upon it at the moment when the sap is rising after its winter's repose to give life and vitality to the branches. He introduces a chemical (how?) into this vivifying agent, and it distributes the coloring composition through every pore and fiber of the tree! When the coloration is terminated the knots and veins contain such a multitude of shades, harmonizing one with the other, that furniture made of it has at once a strange and fascinating appearance.

WOOD FOR CABINET MAKERS.—A Mr. Gerding, who has been prospecting in Mexico for cabinet woods, has discovered three varieties of the walnut—white, red, and black—in great abundance. Of these the black is the most valuable, as it is curly in grain, and as fine as the European or South Sea island wood. The discovery is very important, as walnut is in such universal demand for manufacturing purposes, and has never before been found on the Pacific coast, but has had to be brought from the East.

MASTIC FOR FASTENING INDIA RUBBER ON METALS.—A mastic for fastening india rubber on metals may be obtained by steeping gum lac, in the form of pulverized scales, in ten times its weight of concentrated ammonia. A transparent mass is thus formed, which, at the end of three or four weeks, becomes fluid without the use of warm water. This substance, applied on india rubber, becomes hard, and completely impervious to liquids and gases.—*Moniteur Industriel Belge*.

GOOD HEALTH.

Miasms.

Typhoid fevers are the result of the blood becoming poisoned by miasms, and are much more difficult to cure than to prevent. Farmers may think themselves less exposed to the corrupting influences of miasm than are the dwellers of the city or village, and it is true that the air of the country is more pure than the air of the city, but it is also true that miasms are often found lurking around the farm-house. Nor are they confined to river bottoms and low lands; we have known them to be prevalent in mountain towns. High places are not necessarily destitute of swamps and deceiving animal and vegetable matters, and wherever these are found the seeds of disease are surely generated.

Miasm is such a subtle poison, propagates itself, like yeast, so abundantly, that we desire to call the attention of farmers to the propagating beds to which the farm-houses are particularly exposed, and the first we mention is the cellar. There are wont to be stored lots of vegetables for the wants of the family and the stock. It is the wrong place. The barn should have a cellar just as necessarily as the house. Piles of vegetables will heat and corrupt more or less during the winter, and as soon as spring opens they of course begin to decompose, in order to recombine new vegetation. The windows of the cellar should be taken out, the gangway thrown open, and a good circulation of air kept up in the cellar from this time till late in autumn. Old boards and all decaying timber, as well as old lime and other refuse, should be removed, the whitewash brush applied to the walls, and slaked lime or other disinfectants scattered on the floor.

It will greatly aid in promoting a pure air in the cellar and health in the household if an opening be made from the cellar into the chimney, so that all impurities may find vent up this most convenient channel for ventilation.

Another great generator of miasm in the farm-house, and indeed in all houses, is the sink, which is too often the sink of iniquity and death. If there is anything that will generate vile odors and seeds of disease it is the fermenting compound of soap-suds, dirt, and effete exhalations from the human body to be found in the wash-tub of the laundry.

What to do with the waste water of the sink and wash-tub is one of the problems of country life which is not fully solved. It is too valuable to be lost, and too unhealthy to be kept near the house. To throw it, as many do, from the kitchen door, and leave it there to contaminate the air, is tempting the grim messenger of death to shoot his fatal arrows. If death should ensue, there should nothing be said about the mysterious Providence. The only mystery is that more sickness and death

do not result from the malarious atmosphere of the surface cesspool.

Probably the best mode of ridding the premises of miasm from sinks is to conduct the waste water in iron or cement pipes to a cesspool some distance from the house, and keep this pool well filled with some absorbent, such as dry muck, fine charcoal, or loam. The sink itself should be of iron, and furnished with a valve outlet, so that the gases from the pipes cannot return into the house. A wooden sink is apt to become saturated with the odors generated in the pores of the wood. If wood must be used for sinks, use a solution of copperas frequently to keep them wholesome.

All stagnant water, all marshy places, are fruitful sources of miasm. Let the marshes be drained and the hollow places be filled up. Set out a row of white pines between the house and barn to ward off or absorb the effluvia; keep the homestead every way neat and the air pure, and the health and comfort of the household will amply compensate for the labor.—*N. Y. Times*.

Sunlight.

There is no time in the year when sunlight is so vivifying as in the spring. Perhaps the skillful scientist who can weigh it and tell with how many million tons it presses upon the earth might explain why the ray is more potent as the days lengthen; but that would not change the fact. Instead of excluding it from our houses lest it fade damask and brussels, draw flies and bring freckles, we should open every door and window and bid it enter. It brings life and health and joy. There is healing in its beams. It drives away disease, dampness, mold, megrims. Instead of doing this, however, our careful housekeepers will close the blinds, draw down the shades, lock the doors, shut out the glorifying ray, and rejoice in the dim and musty coolness and twilight of their unhealthy apartments. It is pleasant and not unwholesome during the glare of the noontide to subdue the light and exclude the air quivering with tides of heat, but in the morning and in the evening we may freely indulge the sun bath, and let it flood all our rooms, and if at its very fiercest and brightest it has full entrance to our sleeping rooms, so much the better for us. Wire netting in doors and windows excludes not flies and mosquitoes only, but all other insects, and those who have once used it will continue to do so. With this as a protection from intrusive winged creatures one may quite dispense with shades and shutters, and enjoy all the benefits of an open house without any annoyances so frequent in warm weather. But better the annoyances with sunshine than freedom from them without it.—*Tribune*.

Cures for Felons.

Take common rock salt, dry it in an oven, then pound it fine and mix with an equal quantity of spirits of turpentine. Put it on a cloth and wrap it around the part affected, and as it gets dry put on more. Cures in 24 hours.

Apply a rag wet with tincture of lobelia and keep it constantly wet. Said to be a certain cure.

Poke root (*Phytolacca decandra*) roasted in hot ashes until soft, and then mashed and applied as a poultice, is unrivaled in felons and humors of various kinds. It dissolves them rapidly, or if too far advanced, hastens their suppuration.

A piece of adhesive plaster an inch in width and long enough to go once and a half around the finger, should have spread upon it a surface of caustherial plaster the size of a three-cent piece. This surface should be applied over the tender part and lapped. Allow it to remain for 24 hours at least, and then, if blistering has occurred, the skin may be raised, and beneath it will be found a small opening not exceeding a line in diameter, which penetrates the deep tissue and discharges pus. If the blister is applied during the first three days, this is all-sufficient for a cure; and if the disease has run longer than this, its course is shortened and the cure remarkably quick. The plaster should remain forty-eight hours when applied to the hands of laboring men, a fresh one being furnished at the end of 24 hours. In these cases the opening may be enlarged, as the quantity of pus is greater. The pain is greatly diminished during the action of the blister.—*St. Louis Eclectic Medical Journal*, March, 1876.

THE WATER GAS HUMBO AGAIN.—The Chicago *Times* is the latest victim of the absurd water gas delusion. A "Professor" Kendall, that too cooing journal asserts, has exhibited to its representative "an apparatus which burns from one-fourth to seven-eighths as much water as it does any other combustible fluid," makes gas better than that produced from coke (!) at 50 cents per 1,000 feet, and produces sufficient fire "to do the cooking and washing for six persons for seven days for a like small sum." The *Times* says that "the result overwhelms the mind with its wonderful possibilities," and that "it will astonish the scientist as well as the uneducated and the undisciplined." We fear that all the astonishment regarding the subject will be at the ignorance and credulity of the Chicago paper. Water is nothing but the result of burnt hydrogen, which gave out its heat at the time of its combustion. No fuel can be burnt twice, and it is as impossible to burn hydrogen in water or watery vapor as it is to burn carbon in atmospheric carbonic acid.

The Black Hills Country.

The following article presents a rather discouraging view of the mining and other interests in the Black hills country:

A reaction of feeling against the Black hills mining has set in, and it appears to be supported by facts, though there is no doubt that some of the stories told by returning adventurers were invented purely for a story's sake. A specimen case of the kind is that of a party lately returned to Denver from the mining country with their wagon riddled with bullets, holes, and with one of their number so wounded that his arm was carried in a sling. This they said was the work of Indians, but it afterwards came out that they did not meet with a single Indian; that they shot their own bullets through the wagon, for the sake of making a sensation, and that the wounded man was accidentally hurt during this operation. Yet there is doubtless great danger to life and property in the Black hills region, and the enthusiasm awakened by General Custer's report of a rich gold country was caused by a very exaggerated idea of the value of the gold diggings.

Reports by way of Cheyenne from returning miners say that the number of murders committed by the Indians has not been fully told. The Indians are said to harass the miners constantly, and among the whites themselves there are so many desperate men that life is quite insecure. The miners number about 2,500, but they are distrustful of each other, unharmonious and broken into small parties, and are easily exposed to the mercies of the Sioux. They are frightened at their danger and propose to organize a volunteer force to fight the Indians by Indian tactics, who are said to be growing worse and worse every day. Gold in paying quantities is found in some places, but the expectations of a few months ago are far from realization, and it is said to be the opinion of California miners that there is little foundation for them. Few miners are finding enough gold to pay their expenses, and many are leaving the diggings. Now that the character of the region is so well known, where is the wisdom of an Indian war to punish these murderous red men? It sounds finely to talk of asserting the dignity of the Government and inflicting righteous retribution upon the raiders, but the true policy of the Government is to take the course which will ultimately tend best to secure the peace of the frontier; and how the proposed expedition of Gen. Crook will do that is clear only to those who believe in the policy of extermination. The exploration of the Black hills region has not been a felicitous event, and any further disturbance of the Indians there, so long in advance of the needs of civilization, with so slight inducements for the miner or farmer, would seem a mistaken course. Let the Indians remain undisturbed as long as their lands are not wanted, and let all dealings with them be by honest men, and both Indians and whites will be gainers.

A Cheyenne special says parties of returning Black hills adventurers are continually arriving there, and state that food, ammunition and gold are extremely scarce. They are continually picked off by hostile Sioux, and the latter are on the plains between the hills and Cheyenne. A party recently found four bodies tomahawked, scalped and riddled with bullets, on their way out. The miners are disheartened, and two-thirds of their number have left. Custer City, which once claimed 1,200 souls, has now only 300. Hill City has 200 empty cabins and 20 miners. Mountain City has six cabins and two inhabitants. The Dead Wood and White Wood gulches, where were 1,000 people, contain now but 200. Little B-e-aver and Potato gulches have about 25 men.

A private dispatch from Custer City states that three men, named Williams, Harrison and Brown, the two former from Cleveland, and the latter from St. Louis, while returning from the Black hills, were tomahawked and scalped by Indians near that city on the night of the 16th, and their entire outfit carried off. The bodies were found about 12 hours after the massacre, and taken to Custer for burial.

The body of J. Leggett, a well-known guide, was brought into Custer City on the 3d instant. He was probably killed by Indians. Over \$4,000 was found on his person.—*Colorado Springs Gazette*.

THE WATER GAS HUMBO AGAIN.—The Chicago *Times* is the latest victim of the absurd water gas delusion. A "Professor" Keadall, that too cooing journal asserts, has exhibited to its representative "an apparatus which burns from one-fourth to seven-eighths as much water as it does any other combustible fluid," makes better gas than that produced from coke (!) at 50 cents per thousand feet, and produces sufficient fire "to do the cooking and washing for six persons for seven days for a like sum." The *Times* says that "the result overwhelms the mind with its wonderful possibilities," and that "it will astonish the scientist as well as the uneducated and undisciplined." We fear that all the astonishment regarding the subject will be at the ignorance and credulity of the Chicago paper. Water is nothing but the result of burnt hydrogen, which gave out its heat at the time of its combustion. No fuel can be burnt twice, and it is as impossible to burn hydrogen in water or watery vapor as it is to burn carbon in atmospheric carbonic acid.

W. B. EWER.....SENIOR EDITOR.

JND. L. EDGEEOffice, No. 224 Sansome St., S. E. Corner
of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week. 1 month. 3 months. 1 year.				
Per line.....	25	80	\$2.00	\$5.00
One-half inch.....	\$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing to extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; for three months, \$2.25; for one month, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, June 17, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Centennial at Philadelphia, 385. Answers to Correspondents: Ponderous Mining Works—The Savage Pumping Machinery, 387. The Mechanics' Fair of 1876; The Mindeff Process; The South Yuba Canal and V Flume, 392. Gems and Precious Stones; Owen's Breech Loading Ordnance; How Yahu ble Mines Should be Recognized, 393. Prospected and Worked, 393. Patents and Invention; Notices of Recent Patents, 396.

ILLUSTRATIONS.—Diagram of Machinery Hall, 385. Owen's Breech Loading Ordnance, 393. CORRESPONDENCE.—Some of the Mines of El Dorado Co.; Beyond the Sierras, 386.

SCIENTIFIC PROGRESS.—Micro-Photographs of Blood; Animal Parasites; Alarm Against Suffocation by Gas, 387.

MECHANICAL PROGRESS.—Accurate Measurements; Subterranean Telegraph Joints; The First Railway in China, 387.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 388.

MINING SUMMARY.—From various counties in California, Oregon, Nevada, Arizona, Montana and Idaho, 389-90.

USEFUL INFORMATION.—Hanging Shafting; How to Paper a Wall; Classification of Nails; Staining Growing Wood; Wood for Cabinet Makers; Machine for Fastening in the Rubber on Metals, 391.

GOOD HEALTH.—Miasmas; Sunlight; Cure for Fevers, 391.

Mining Accidents.

A MAN'S FACE MANGLED.—An accident occurred in the Bowman incline recently where a man was seriously injured and perhaps disfigured for life. The injured man was coming to the surface, riding on the rope in front of the car, when the car ran against the end of a section of the iron with which the wooden track is laid and which had become detached from its fastenings. The car was thrown from the track and the man thrown violently against the end of the protruding iron. The bones of his nose were shattered and crushed and his face and scalp frightfully mangled, though his sustained no injury in a vital part. This riding on the rope is a common though dangerous practice in this mine, this being the second accident which has occurred from the same cause. There is a footway for the men to go up or down, but to save time and sole leather they perch on the rope when the car is going up.—Reese River Revue.

DROWNED IN A SHAFT.—This forenoon, June 12th, a miner named John Martin, working in the Lane & Fuller shaft, Pacific Co., pushed a car into the shaft and was drawn in after it, falling from the 400-foot level to the 550-foot level, a distance of 150 feet, 75 feet of the fall being through space and 75 feet through water. As soon as the accident was made known men were put at work bailing the water and grappling for Martin's body, which was recovered about two o'clock this afternoon. The deceased went to work in the mine for the first time this morning, and Mr. Henan, the Superintendent, attributes the accident to Martin's lack of knowledge of the mine.—Reese River Revue.

Ponderous Mining Works—The Savage Pumping Machinery.

It cannot be doubted that California possesses many advantages in the manufacture of the magnificent machinery. The inventive spirit, inspired by the thoughts of treasures but lightly hidden, serves itself to cope with any requirement, no matter how great or difficult. Possessing the true California quality of enterprise, the manufacturing skill and power follow close upon the thought of the inventor, and the brightest idea is speedily embodied in practical and effective machinery. The result is that the industrial spirit on this coast is more alert, active and progressive than in the older States. Continually gaining strength by past achievement, it pushes forward with new power and vigor. It shrinks from nothing; it achieves everything. We claim that nowhere else in the world is there more spirit, enterprise, inventive and executive ability than among our manufacturers of machinery.

No small part of our success in this direction is due, doubtless, to the fact that our resources are so rich and so accessible. The speed with which immense values are drawn from our mines leads to free investment in means to obtain them. The demand says: "Give us what will do the work, the reward is ours." In answer to such a call our enterprising manufacturers are continually improving their patterns, enlarging their facilities and stimulating their inventive power. This result is growth, progress and improvement, which are an honor to the State, because they establish an independent self reliance in our industries. Everything which the workers of the coast requires the manufacturers of this coast can supply.

We are reminded of the hopeful and promising condition of our manufacturers continually during our inspection of the foundries and workshops, and we have a fresh illustration of it this week in a splendid piece of mechanism which we will describe.

The pumping machinery for the Savage mine, recently completed at the Pacific iron works in this city, is the most complete and extensive ever made on this coast, so in the matter of design and workmanship is alike creditable to the skill of our mechanics and the capacity of our iron works. The engine is what is known as a direct acting compound non-condensing engine, and is from an original design by Mr. William H. Patton, consulting engineer of the Savage mine. It is a very massive affair, being about 40 feet in length and weighing upwards of 100 tons. This engine connects directly with the pump box at the head of the shaft, without the usual intervening crank and gearing. The valves are connected with the Davy differential valve gear, which is operated by an independent engine, by which the strokes of this pump can be varied without any reference to the motion of the main engine.

A somewhat detailed description of this mammoth machinery will doubtless be of interest to the general reader. The engine consists of two horizontal cylinders. The first or initial cylinder is 27 inches in diameter and 8 feet stroke. The second is the expansion cylinder, and is 48 inches diameter and 8 feet stroke. These two cylinders are placed in line and connected by one piston rod, by which the pistons of both cylinders are operated. Attached to this opposite end of the large cylinder is the bed plate with slides and cross-head, to which is attached the connecting rod, which connects directly with the pump box. The steam enters the first cylinder at an average pressure of 90 pounds per square inch, and exhausts into the large cylinder, where it expands down to a pressure of not more than 5 or 6 pounds, thus utilizing the whole expansive power of the steam, and this, we may remark, is the secret of the great economy of the compound engine.

The engine is so arranged as to permit the attachment of a condenser when it shall become necessary to increase its power as the shaft increases in depth. This machinery will now have a lift of about 2,500 feet, but it is capable of raising a column of at least 4,000 feet in depth, with a capacity of 30,000 gallons per hour.

The pumps are stationed every 250 feet in the shaft, each pump being supplied from a tank filled from the pump below. The sinking pump, which is to follow the workings of the shaft, is 20 feet stroke and four inch metal, weighing some 12 tons, being strong enough to stand the heaviest blast.

The pump rod is made of 14-inch square timber, heavily braced with iron straps, and extends to the bottom of the shaft. The enormous weight of this rod is counterbalanced with balance bobs, stationed every 500 feet in its length.

The engine, with line of pumps, bobs, etc., weighs something over 500 tons, and will cost the mine when put in place about \$400,000. The foundations for this machinery are of the heaviest and most substantial character, being made of cut stone upwards of 30 feet in depth.

The entire machinery has been constructed under the immediate direction and supervision of Mr. Geo. W. Pogg, the Superintendent of the Pacific iron works, to whose skill and efficiency the company are largely indebted for the superior character of the work and the unprecedentedly short time in which the order has been executed; the work having all been done

and shipped inside of 90 days. Messrs. Rankin & Brayton, the proprietors of these works, have recently added largely to the capacity of their establishment by the erection of new buildings and the addition of new and improved machinery, so that it is now one of the largest and best equipped in this country.

The Mechanics' Fair of 1876.

California is, according to all accounts, very poorly represented at the Centennial. The richest States in the Union, the State whose progress and development are entirely without a parallel in this history of the world, whose riches and products of all kinds are not reached by any other, has left the chances untaken to show fully to the world at large what industries can be developed, what prosperity can be gained in a congenial climate by a bold and enterprising population.

This is decidedly to be regretted, and our pride as Californians should feel considerably shaken. But still there is another chance left for us, a chance at home, to show to the people of the old world, who we hope will this year, in large numbers, pass over to our State, what the main nerve of California's prosperity consists in, to show them in a condensed form every branch of industry practiced here, and let them understand that we, the remotest of all States of the Union, are by no means the last in manufacture, intelligence and enterprise. We refer to the industrial fair to be held in San Francisco this year. Let every man in California help to make it a Centennial show of our own. Surely we have enough to exhibit. There is, before and above all,

Our Mining Interest.

Which should and must at all hazards be properly represented. Inventors and miners, patriotic you all are, show yourselves willing to spend something extra in favor of our Centennial exhibition. Send on the ores and all varieties of them from every mine in California. Let the manufacturers of milling machinery co-operate with the mine owners to have these ores worked and tested in their machinery before the people; make it a grand competition of riches and wealth, and a grand race of the genius of inventors and enterprising people in the mode of extracting them. Every phase of milling, from the receiving of the crude ores to the refining of the bullion, should be shown, and there would surely be no better chance for those who claim to have found superior methods of reduction to bring them before the people and have their inventions properly appreciated.

Hoisting and pumping machinery has another good chance at competition, and not only for competition, but for the admiration of intelligent men from all parts of the globe. Rock and prospecting drills may show their real merits, and we hope they may be represented in full numbers to join in a friendly race. But even the old arrastra process and Chilesen wheel into its latest improvements, the roller pan and giant wheel should not stay away; their working will be of the highest interest to visitors and of material benefit to exhibitors.

All Other Industries

Should be in proportion: powder and dynamite, sugar refineries, chemical manufacturers of all kinds, fresh and dried fruit, corn, wheat and other important crops, should be there, and we will have a show of the products of our own prosperous State that will spread the fame of California over the world, and make every Californian proud to belong to the most enterprising and enterprising State in the Union.

The Mindeff Process.

We have, in the Press of the 23d of May, thoroughly ventilated the question of the reduction of ores by the gas process; we have shown that so-called rebellious ores, that is, those containing copper and iron pyrites, are not affected by the gas; we have, of course, only spoken of copper and silver ores, never dreaming that an attempt on the credulity of the people might be made at gold ores. But we have still to learn. We conceded to the inventor all his theories, even the ones on sulphides of silver, which was promised by him to be practically proven for some time, but the idea of working rebellious gold ore by the gas process is so perfectly preposterous that we have to give it a slight ventilation.

Rebellious gold ores we call those in which the gold is found in iron or copper pyrites; but you must be aware that it always appears metallic, that it is not in a chemical combination, but free like all other gold ores, (we refer to an article on another page of the Press). Now, as the main and in fact the only point of the Mindeff invention consists in the metalization of metallic oxides—the pyrites are not affected by it—what does he do with his invention where he has metals direct? Does he claim a superior roasting furnace? We never heard of that, and surely the construction of the one at the works does not warrant such an assumption. As long as Mr. Mindeff, or any other inventor, keeps within the scope of legitimate investigations we are willing to do all we can to show the good points of their inventions, but when common sense even is so directly challenged it is our duty to give the warning.

G.

The South Yuba Canal and V Flume.

(From our own Correspondent.)

A canal 123 miles long, discharging 147,000,000 gallons (actual measurement) per day, is something not unworthy of notice; and such is the South Yuba canal, of Nevada county, Cal.

Tapping the South Yuba river about two and a half miles from the line of the Central Pacific railroad, this aqueduct winds its serpentine course southwest towards Bear valley, where it divides into two branches, the main arm running toward Nevada City, and the minor one toward Dutch Flat.

Of the main or Nevada City branch, about 120 miles consists of a wooden water course, known to miners as "fluming." This huge combination of boxes is carried over trestles, in some instances (as at Sleep hollow) to the height of 130 feet. Over another portion of the route engineering difficulties of a different character have been overcome. Running along the steep and rugged sides of the Sierras for some five miles, the canal stretches its course around the face of a perpendicular cliff 100 feet high, having its bed hewn in the solid rock, accessible to workmen only by means of slings and scaffolding.

The main ditch supplies many important mining camps. Among these are Chalk Bluff, Scotch Flat, Quaker Hill and Blue Tent. It also supplies the water works of Nevada City and Grass Valley, and the "V Flume" lumber canal.

The Dutch Flat branch of this South Yuba canal was built in 1864, and supplies a portion of the mines of Dutch Flat, Gold Run and other points. From this source alone this former town is supplied with 63,000,000 gallons of water daily. From Dutch Flat there is a partial connection with Auburn, and as the water is of the best quality, many engineers are of opinion that even San Francisco might be supplied from this source. It is certainly more feasible than the scheme of drawing such supplies from Lake Tahoe.

To guard against the lowering of this water level of the South Yuba river, the South Yuba canal company have erected several large reservoirs, one of which, although purely artificial, has secured the term of "lake." This is Meadow lake, which covers over one hundred acres, and has a capacity to the extent of 1,050,000,000 gallons. Fordyce dam is another reservoir of immense capacity. It is formed by damming up the South Yuba river at a point some 18 miles from Cisco. It is 45 feet deep and covers over one and a half square miles. It has a water shed of 15 square miles, and when completed will hold 5,000,000,000 gallons of water. These reservoirs enable the company to maintain 7,000 miners' inches of water in their canal throughout the year.

The South Yuba canal company was organized in 1852, by the consolidation or absorption of the Rock Creek, Gold Flat and Deer Creek ditch companies. This late lamented Charles Marsh was among the foremost spirits in this enterprise, and held the position of Secretary up to the time of his death. James Whartenby, Esq., has occupied the position of President ever since the inception of this company.

The V Flume.

This traveler on the Nevada City over the narrow gauge railroad can hardly fail to observe a long line of lofty trestle running from the Town Talk tunnel N. E. till lost to the view above this town. This is the so-called V flume, an aqueduct built by the Nevada and Grass Valley water and lumber company for the purpose of conveying water and lumber towards the latter town.

The length of the V flume is 16 miles, and in several instances it runs over a trestle 100 feet from the ground. It was completed in 1874, and consumed 1,000,000 feet of lumber and 30 tons of nails in its construction. It is capable of floating down the heaviest timber and has a capacity of 200,000 feet per day. Up at its junction with the S. Y. canal several saw mills are operated by its current; the largest of these is worked by a 14-foot "hurdy-gurdy" wheel, with a pressure of 344 feet and requiring 150 inches of water to move it.

The lumber region contiguous to this line of the V flume is extensive and is said to produce very superior timber. The new Nevada County railroad will no doubt add considerably to its importance. The owners of the S. Y. C. and V flume companies are not numerous, and we believe that none of the stock of either company has been in the market, or is likely to be.

J. Earl Brown, Esq., is the Superintendent of both interests, and combines in himself the best elements of the wide-awake business man and the courteous gentleman.

Answers to Correspondents.

F. J. Guss, Rye Valley, Oregon.—It is by no means the carbon which is troubling you in the arrastra. We will, in a later number, publish a complete description of the process. At present we have turned over your communication to Mr. E. G. Gaertner, M. E., No. 206 Front street, S. F., an expert who has our confidence, from whom you will receive all the information desired.

THE "HOME EDITOR" of the MINING AND SCIENTIFIC PRESS, unavoidably absent for several weeks, is expected back before our next issue.

Gems and Precious Stones.

(Written for the Press by HENRY G. HANES.)

(Continued from last week.)

E. Emerald, Beryl, Aquamarine.

These are varieties of the same mineral. They are silicates of alumina, containing glucina, with chromic oxide, peroxide of iron, lime, magnesia and tunic acid as impurities. The deep green varieties, colored by oxide of chromium, are called emeralds. Lighter shades of green or nearly opaque varieties are known as beryl, while a pure pale green or pale sky blue crystal is the aquamarine.

The common beryl is generally only imperfectly translucent, and owes its color to oxide of iron. Disregarding the minute quantity of iron or chromium which imparts the characteristic color to the varieties, the composition of pure beryl is as follows: Silica 66.8, alumina 19.1, glucina 14.1=100. Crystalline form, hexagonal. Hardness, 7.5-8. It may be scratched by a good file, but with difficulty, scratches glass easily and a quartz crystal slightly. Specific gravity 2.68. Fracture conchoidal. B. B. alone infusible—a thin splinter may, with great care, be rounded on the edges by partial fusion. With borax a transparent glass is formed with beryl and a deep green one with emerald. The powdered mineral dissolves in a bead of microcosmic salt without leaving a skeleton of silica. When heated to redness and thrown into water the emerald falls to pieces. It is not acted on by acids.

The most celebrated locality where the emerald is found is in the United States of Colombia, State of Boyaca, at the emerald mines of Muzo, near Santa Fe de Bogota.

These mines were worked for many years by a French company, whose lease expired in the year 1874. A large quantity of emeralds, and of great value, have been taken out of the principal mine. The stones were all sent to Paris to be cut. The emeralds occur in so minute and lie in bunches, or what would be called pockets in a gold mine. Sometimes months pass without any being found, while sometimes 100,000 carats are found in a few days. It is found to be very difficult to estimate the value of an emerald before it is cut; much depends on the depth of color and freedom from flaws. A stone of deep color, free from flaws and perfectly transparent, may be worth \$100 per carat, while some of inferior quality are sold very cheap. A French traveler discovered, in the mountains of Zaharah, in Egypt, an ancient mine of emeralds, which shows signs of having been extensively worked. This was no doubt the source from which the ancients obtained the emerald.

History shows that the emerald was known in remote ages. Necklaces of emeralds have been found in Etruscan tombs. This stone is mentioned in the Bible, and it has been shown that both the emerald and beryl were among the precious stones in the breast plate of the high priest.

In ancient Peru the emerald was used in the worship of the goddess Esmeralda, who was believed to reside in an enormous emerald of the size of an ostrich egg. The priests induced the people to present offerings of emeralds to this deity, which led to the collection of great numbers of these gems in the temples. At the conquest they all fell into the hands of the Spaniards.

A perfect emerald may be regarded as a wonderful production of nature; this fact is so well known that the expression "an emerald without a flaw," is proverbial and is taken in a double sense, being used to express the idea that perfection is almost unknown.

The emerald ranks next in value to the ruby. In England a stone possessing the requisites of the educated taste of amateur is worth from \$100 to \$200 per carat. The value of the emerald does not increase in the ratio of the diamond or ruby.

The aquamarine was formerly very valuable, but it is not so at the present day, having gone out of fashion.

Beryls are found in several localities in the United States. The most celebrated is Acworth, New Hampshire, where gigantic crystals have been found; one weighed over 300 pounds. Beryl may be looked for in granite rocks, and the emerald in clay slate, in which matrix it is found in the celebrated mines of Muzo, mentioned above.

Fine specimens of aquamarine have been brought to California from the deserts of Arizona, where they occur with other precious stones. A very fine specimen is one in the collection of the State University at Berkeley. Where such fine aquamarines are found it is worth while looking for emeralds, and I hope to hear of their discovery in that country.

Tourmaline, fluor spar and apatite are sometimes sold as emeralds, but they do not possess the physical properties of the true emerald. A paste imitation is made which can hardly be distinguished from the emerald.

Prior to the opening of the Centennial exhibition, it was feared that poor accommodations and exceedingly high charges would universally prevail at the Philadelphia hotels during the Centennial, but by reference to our advertising columns it will be seen that one of the most commodious, conveniently located and well recommended hotels in that city offers very reasonable rates. We allude to the Park View hotel.

Owen's Breech Loading Ordnance.

As an important Pacific coast invention we place before the readers of the MINING AND SCIENTIFIC PRESS the following description of a new device for breech loading guns of heavy caliber. The invention was made in Nevada and patented through Dewey & Co.'s Patent Agency. It is well described in the patent as follows:

This invention relates to an improved arrangement or device for loading cannon of all kinds through the breech; and it consists of a peculiar interior configuration of the breech of the gun, together with a breech-key, so shaped as to enter the breech by a direct movement from the rear, and then by a quarter turn close and lock the same securely.

In the accompanying drawings, A represents a cannon having any desired construction of barrel and bore. The breech arrangement consists of a key-chamber, B, at the base of the bore and key-slot C. The key-chamber is a cylindrical space formed within the breech of the gun immediately behind the powder-chamber, with its axis coincident with that of the bore. Its transverse diameter is much greater than that of the bore, and its axial depth should be sufficient to accommodate a block of metal capable of resisting effectually the rearward impact of the charge when the gun is fired. The angular recesses within this cham-

OWEN'S BREECH LOADING ORDNANCE.

ber should be rounded in slightly for obtaining greater strength along those lines. The key-slot C is an oblong opening leading directly through the cascabel at the rear end of the gun along its axis into the key-chamber. Its length or greater diameter, which, for obvious reasons, should be placed vertically, is precisely equal to the diameter of the key-chamber, while its width or lesser diameter is considerably less, though still a little greater than that of the bore. Its axial depth should be a little more than that of the key-chamber, about three times the diameter of the bore being deemed a fair and full allowance for the united depth of both chamber and slot. Where this slot enters the key-chamber two stout shoulders, d, d, of solid metal are left, one on each side of the slot,

used each shell is made to serve that purpose. The thickness of the head block in the axial direction is made to correspond with the axial depth of the key-chamber, so that when it is pushed home, and a quarter turn given to it, the inclined surfaces on its posterior face gliding upon those of the shoulders of the breech cause it to bind firmly in a fore and aft direction within the key-chamber, thus securely closing and locking the breech of the gun.

A guide or carrying frame is also herein illustrated, which is probably the most convenient and simple device for the purpose on guns of ordinary weight and caliber; but for very heavy guns a radical modification of this arrangement has been devised, and might be substituted with advantage.

This carrying frame consists of, first, a collar or a swivel-barrel, I, which embraces the stem E of the key over its whole length, from the head-block to the handle, so as to hold the key steadily while it turns freely on its axis in the collar; second, a slide or guiding stem, J, which is somewhat longer than the collar I, and which moves freely in and out under the gun on a friction-roller, M, which is secured in a bracket, N, fastened to the under side of the breech; and, third, an upright part, P, which connects the two preceding parts, and holds them firmly in position parallel with each other. The extreme front end of the slide E is curved downward like a claw, and should be so shaped as to catch upon the friction-roller when the slide is drawn backward to its full length, and pre-

Fig. 1.

vent its complete separation from the bracket, while it allows the rear end, with the key, to drop down and rest upon the ground or hang upon the roller. In this position the gun is ready for loading, which may be accomplished very conveniently by means of a tray with a very thick bottom, and a movable handle held loosely in a collar at its rear end. Upon this tray the charge is introduced into the breech through the key-slot, and then by means of the tray-handle, used as a rammer, pushed forward out of the tray and into the bore of the gun. The tray is then removed and the key lifted and pushed home, where by a quarter turn upon its axis it locks the breech, and the gun is ready for firing.

The firing may be effected by means of a per-

Fig. 2.

OWEN'S BREECH LOADING ORDNANCE.

with their faces looking forward into the chamber. These faces are finished by giving to each a true spiral inclination of a low degree of pitch around the axis of the chamber. The breech-key consists of a stout stem, E, carrying upon its front end an oblong solid head-block, F, which is fixed upon it transversely, while upon the other end is fastened transversely to the block a lever-handle, G, by which the key is moved and turned. For the sake of greater strength the stem and head-block should be wrought together in one solid piece of metal, preferably of steel, but the handle need only be keyed upon the stem. The head-block of the key is shaped to fit and fill the key-slot somewhat loosely, so as to pass easily through it either into or out of the key-chamber.

The front face of the head-block is made plain and level; but its rearward face has a circular projection, H, rising from its central portion equal in diameter to the width of the block, from the center of which projection the stem, E, of the key issues. The surfaces of this face, nearer the ends of the block, are finished in true spiral inclines to correspond with the inclined faces of the shoulders in the breech, upon which they are made to glide and bind when the block is turned toward a transverse position in the key-chamber. These spiral inclines run out upon the sides of the central projection of this face without joggling or interfering with each other.

For a gas-check, where metal shells for the powder are not used, the bottom of the bore should be turned out so as to receive a ring of suitable metal, and the rearward edge of this ring should project very slightly into the key-chamber, so as to bear the impact of the front face of the head-block when the breech is strongly locked, but where metal shells are

How Valuable Mines Should be Recognized, Prospected and Worked.

(For the Press by E. G. G.—No. 3.)

It will now be in place to consider the different classes of ores found in nature.

1. Gold Ores.

There are but two varieties of gold ores found.

A. Metallic Gold.

Its specific gravity is 19 to 19.65. It can be dissolved only in nitro-muriatic acid and can be precipitated out of its solution by sulphate of iron. In nature it is rarely found pure, but generally alloyed with more or less silver; this percentage of silver gives rise to the expression, the fineness of the gold is so much, taking 1,000 as a basis and subtracting the percentage of silver in the alloy by weight. One ounce of fine gold (1,000 fine) is worth \$20.67. The U. S. gold coins are 900 fine.

The chemical properties of the gold, its unchangeability in the atmosphere, in water and simple acids, its non-oxidizing in fire and its fine color and malleability, make it, aside from its international use, one of the most valuable metals.

B. Sylvanite (Telluride of Gold).

The color of this metal is light steel gray, scratch grey, hardness 1.5 and specific gravity 5.7. Its composition is tellurium 59.40, gold 26.30, silver 14.30.

An easy test for telluride is its quality to give in concentrated sulphuric acid with gentle heating a fine red solution, which discolors upon water being added, and gives a gray precipitate. However, the existence of this variety is still disputed, some alleging that by microscopic analysis it is evident that the gold and tellurium are only mechanically mixed.

This is also the case in the gold bearing copper and iron pyrites or sulphurets. It is an opinion widely spread that the gold contained in them is some other composition; to the contrary it is all metallic gold and of no chemical combination with the sulphides of iron or copper surrounding it. The mode of working it we will explain at a later day.

Several subordinate varieties of gold ores are too rarely found and too difficult to distinguish to be taken into our enumeration. Certain it is that gold appears only metallic and pure or alloyed with silver, platinum and tellurium.

The ordinary test for gold is on this account very simple. Spooning or washing in a horn spoon after dry pulverization is the best mode. This has come to us from Mexico, and every miner on the coast is versed in the use of the spoon. Panning is used for the testing of auriferous gravel and just as well known. If you have sulphurets which are a great hindrance to seeing the gold and sometimes contain it in very minute particles, it will have to be roasted until all the sulphur in shape of sulphurous acid has evaporated, when the washing can be done by the spoon and the gold will be readily seen. Its peculiar bright yellow color makes it easily distinguishable from mica and iron pyrites.

The assaying of gold ores in a simple manner we will give, together with that of silver ores, in a later number.

Mechanics' Institute.

On the evening of June 10th, the recently elected trustees of the Mechanics' Institute were installed by N. W. Spanning as follows: A. S. Hallidie, H. L. Davis, George Spanning, Asa R. Wells, James Dimry, J. E. Setson and James Spiers.

After the installation the Board of Trustees met and elected A. S. Hallidie, President; P. B. Cornwall, Vice President; H. L. Davis, Treasurer; D. E. Hays, Secretary, and James Spiers, Corresponding Secretary.

The annual report of President Hallidie was presented at the meeting. In it he called attention to the advisability of securing a new location and erecting thereon a new building for the use of the Institute. The report shows that during the past year 5,664 volumes have been added to the library, which, added to the number of books, as per last report, will make a total of 27,266 volumes. The number withdrawn from the library averages 7,840 per month, or 94,080 annually.

During the year, 723 ordinary and 10 life members have joined the society, and the total number of members is estimated at 2,000.

The receipts in the general fund during the year amounted to \$41,273.92; \$6,755.15 was obtained from membership dues; \$17,000 was borrowed from the Union Insurance Company, \$2,050 received from life membership dues, and \$5,316 from the last industrial fair. The disbursements from the same fund amounted to \$40,188.20, \$12,466 being paid out for books, and \$7,561 for improvements and repairs. This leaves a balance of \$1,085.72 in the treasury. The receipts in the sinking fund amount to \$3,128.40 and the disbursements \$1,444.50, leaving a balance in the fund of \$1,683.90. The gross assets of the Institute are placed at \$119,825.35 and the liabilities \$22,567, leaving as net assets the sum of \$157,258.35.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

SAN FRANCISCO, CAL.**SODIUM AMALGAM.**I am prepared to furnish Sodium Amalgam for \$1.50
per pound. Although the price is low, my reputation is
a guarantee of its purity. Sodium being now much
cheaper than formerly, the miner and millman should
have the advantage of it. The temptation to adulterate
the article being so great, consumers are advised to
call for my manufacture when ordering from wholesale
dealers, with an assurance on my part that the quality
will be the best. Zinc is sometimes substituted for
sodium, to the great disadvantage of the consumer.
The following are the tests for pure Sodium Amalgam:
Shaken up with water it must be wholly decomposed,
the mercury remaining perfectly fluid and the water
becoming strongly alkaline.HENRY G. HANKS,

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency the following are worthy of mention:

RAILWAY CARRIAGE.—Emanuel Blochman, S. F. The object of this invention is to provide certain improvements in railway carriages, and they are more especially applicable to those carriages which are intended for the cheaper classes of travel. In those cars which are intended for second-class and emigrant passengers very little accommodation is usually found for the travelers, and when long journeys, such as a transcontinental one from the East to the Pacific slope are to be made, much suffering is often occasioned. Mr. Blochman's invention contemplates the accommodation of more passengers, and at the same time providing all of them with sleeping accommodations at night.

The car employed is one in which part of the floor which lies between the trucks is lowered so as to give a considerable height, and this height is divided into two stories, so as to give two series of seats, one above another. The passages on the lower floor are made along the sides and the upper passage is made in the center. The seats on the lower floor are placed longitudinally, back to back. This arrangement brings the seats beneath the passage, so that there will be plenty of room for those sitting, while the seats in the upper part being situated above the side passages will thus allow of those passengers being made high enough for the purpose of walking. The upper passages, being centrally located, will be beneath the raised roof and give ample height in this part. The seats have extensions, which may be raised at night so as to stand on the same plane with the seat, thus making it broad enough for a bed for two. Beneath the seat is a folding extension, which, being laid horizontally, will be on a level with the raised floor, and this surface gives a bed for two more. The backs of the seats are hinged at the top to a suitable frame, which may be made to slide up on upright timbers between each section, so as to elevate it to a suitable height above the seat. The back may thus swing out and its outer edge supported by hangers from the ceiling. This gives another bed, so that there will be three tiers of berths, one near the floor formed by turning down the extension, one formed by the seat and its extension, and the third by turning up the wide back so as to lie horizontally above the seat. On the upper floor the seats are provided with backs which may be turned down, being hinged at the bottom, so as to lie on the same plane with the seat behind it, and these will form roomy beds for those passengers who occupy this floor. Access may be had from the ends of the seats to the lower central floor by a short flight of steps. Ample arrangements are made for ventilating all parts of the car, and the inventor is enabled by his method of construction to accommodate at least 70 per cent. more passengers than by the ordinary way, and at the same time give more than one-half of the passengers a place to lie down and sleep at night.

AFFAIRS IN CUSTER.—A gentleman direct from Custer, says the *Denver Tribune* of May 31st, informs the Nebraska press that the people there could not remain. The road from Laramie to Custer is swarming with Indians, and he does not believe it can be kept open. No confidence is felt in Crook's expedition for immediate relief. It is believed by this informant that the people now there will make their way out of the country by way of the Missouri. He received a wound in the hip from an attack on the train with which he came out.

Pleasant and Satisfactory.

HAMILTON, N.Y., May 28th, 1876.

To Messrs. Dewey & Co., Patent Agents:

GENTLEMEN—I write to acknowledge the receipt by express of the U. S. letters patent on my invention for breech loading ordnance, and to tender you again my very sincere thanks for the careful attention you have bestowed upon my application since I first placed it in your hands for the evident great interest you have manifested in it, and for the uniform patient and cheerful courtesy which has constantly marked your correspondence in reference to it. I have had some dealings with other agencies in the same line in times past, and I can assure you that my correspondence with you has been more pleasant and satisfactory than with any others, and I shall always take great pleasure in recommending your agency to any and all my acquaintances without hesitation or reservation, as I should certainly prefer to entrust my own business in your hands should I have any to transact in the same line hereafter. Yours, etc., J. R. N. OWEN.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. TEARS—San Francisco.
B. W. CROWLEY—California.
G. W. MCGHEE—Santa Clara county.
J. M. MCARTHUR—Los Angeles, Santa Barbara, Ventura, San Bernardino and San Diego counties.
A. C. ENOX—El Dorado county.
F. A. SCOTFIELD—Sonoma county.
O. N. WISE—Santa Cruz county.
CHAS. E. SAJOUS—Philadelphia.

NOW'S THE TIME.—Everybody interested in mining and agriculture should subscribe for the Centennial year for either the *RURAL* or the *SCIENTIFIC PRESS*, published by Dewey & Co., San Francisco. They are the best journals of the kind in this country, and deserve the support of all those whose cause they espouse. Everything of interest connected with the Centennial, appropriate for these papers, will be collected. Send in your names.—*Mountain Messenger*.

PLACERVILLE, June 7th, 1876.

MR. JOHN L. BOONE:

Dear Sir—Yours of the 5th inst. received this morning. I am glad to have occasion to express the feeling I have in regard to the handling of my patent applications by your firm. I am much gratified by your success, and more than satisfied by the expedition and promptness which has characterized the transaction of the business in every particular.

Respectfully yours, HILAND G. HULBURD.

THE EXPLORES', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy, containing 673 pages and 83 engravings. By J. S. Phillips, M. E. Price, cloth, \$10.00; in leather, \$12; postage 50 cts. Sold at this office.

"SPEAKS WELL," ETC.—We would return thanks for an exchange and back numbers of the *MINING AND SCIENTIFIC PRESS*, published by Dewey & Co., of San Francisco, Cal. It is a well edited, interesting, and valuable journal, and speaks well for our Pacific neighbors.—*U. S. Mining and Manufacturing Journal*.

THE IRON which commonly prevails among people of unclean habits and impure blood, and usually induces the ordinary expedients for its removal, can be quickly expelled by a few shavings with GLENN'S SULFUR SOAP. Sold everywhere.

WOODWARD'S GARDENS embraces an Aquarium, Menagerie, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

1776.

1876.

CENTENNIAL EXPOSITION.

PARK VIEW HOTEL,

Corner 29th and Poplar Streets,

Opposite Fairmount Park,
PHILADELPHIA.

This Extensive First-class Hotel consists of thirty (30) adjoining and communicating buildings, having a frontage on Twenty-ninth Street of 185 feet, and on Poplar Street of 375 feet.

The Buildings are partly pressed brick and partly Serpentine stone, entirely new, having been built for the purpose of handsome private residences, with all the modern conveniences, thus affording more comfortable apartments than perhaps any other hotel in the city. Every room is furnished with new and substantial furniture, consisting of Beds, Carpets, etc., and seven hundred (700) guests can be comfortably entertained. It will be seen that this Hotel furnishes unusual advantages for families or parties desiring contiguous suites of rooms, a feature which will especially recommend itself to Lodgers and other organizations. The Location of this Hotel is equal, if not superior, to any place in the city. There is easy and rapid access to the Exposition, to and from all the Railroad Depots, as well as to every portion of the city. It is situated on high ground, within 200 yards of and overlooking Fairmount Park, and in the immediate neighborhood of Girard College, Girard Avenue Bridge, Zoological Garden, Fairmount Water works, and Lemon Hill, the latter place being one of the most delightful localities in the Park where Musical and other Entertainments will be kept up by the city throughout the season.

All places of amusement and interest in any part of the city may be readily reached by the Girard Avenue Line and the Union Passenger Railway, the care of the latter running directly by the Hotel. All other Passenger Railway Lines at convenient distances.
Lodgings, per Day.....One Dollar.
Breakfast.....Fifty Cents.
Dinner.....Seventy five Cents.
Supper.....Fifty Cents.

No Mesits to be paid for unless ordered or taken. The Houses being built of brick and stone, are far less liable to fire than many of the wood structures now put up for Centennial purposes. There will be connected with the Hotel Private Watchmen, Fire-proof Safes, Biggame Rooms, etc., for the care and protection of property. The Hotel is supplied with Thirty Bath Rooms, with all modern appliances. Rooms may be secured in advance for any time during the Exposition. The Hotel will be conducted with the special view to accommodate visitors to the Centennial Exposition. Readers of this will please send for illustrated circular, free.

[illegible]

Iron and Machine Works.

WM. HAWKINS. T. G. CANTRELL

HAWKINS & CANTRELL,

MACHINE WORKS,

210 & 212 Beale St.,

Near Howard, - - - SAN FRANCISCO.

MANUFACTURERS OF

Steam Engines and all kinds of Mill and Mining Machinery.

Also manufacture and keep constantly on hand a supply of our

Improved Portable Hoisting Engines,

From Ten (10) to Forty (40) Horse Power.

N. B.—Jobbing and Repairing done with Dispatch.

FULTON

Foundry and Iron Works.

HINCKLEY & CO.,

MANUFACTURERS OF

STEAM ENGINES,

Quartz, Flour and Saw Mills,

Hayes' Improved Steam Pump, Brodie's Improved Crusher, Mining Pumps, Amalgamators, and all kinds of Machinery.

N. E. corner of Tehama and Fremont streets, above Howard, San Francisco.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868.
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggin,
James D. Walker.

WM. H. TAYLOR.....President
JOSEPH MOORE.....Vice-President and Superintendent
LEWIS R. MEAD.....Secretary

24v17-19

THOS. PENDERGAST. HENRY S. SMITH.

ÆTNA IRON WORKS.

MANUFACTURERS OF

IRON CASTINGS

and MACHINERY,

OF ALL KINDS.

Fremont Street, bet. Howard and Folsom,

SAN FRANCISCO.

SHEET IRON PIPE.
THE

Risdon Iron and Locomotive Works

Corner Howard and Beale Streets,

Are prepared to make SHEET IRON AND ASPHALTUM PIPE, of any size and for any pressure, and contract to lay the same where wanted, guaranteeing a perfect working pipe with the least amount of material. Standard sizes of railroad Car Wheels, with special patterns for Mining Cars. These small wheels are made of the best Car Wheel Iron, properly chilled, and can be fitted up with the improved axle and box—introduced by this company, and guaranteed to outlast any other wheels made in this State.

24v22-3m All kinds of Machinery made and repaired.
JOSEPH MOORE, Superintendent.

Miners' Foundry and Machine Works,
CO-OPERATIVE,

First Street, bet. Howard and Folsom, San Francisco.

Machinery and Castings of all kinds.

McAfee, Spiers & Co.,

BOILER MAKERS
AND GENERAL MACHINISTS,

Howard between Fremont and Beale, st., San Francisco

TULLOCH'S AUTOMATIC ORE FEEDER.

The TULLOCH AUTOMATIC ORE FEEDERS have been practically tested during the last year and a half in twenty-seven mills, of from five to eighty stamps each, and have, in every case, given perfect satisfaction. Refer to the following Mills: California, Con. Virginia, Northern Belle, Leopard, Trench, Humboldt, Douglas, Phoenix, Hite, Crescent, and others. Prices Reduced. Send for Circulars.

F. OGDEN, Sole Agent,

417 Market Street, San Francisco.

RIDER COMPRESSION AIR ENGINES

HAVE NONE OF THE FAULTS OF THE OLD CALORIC ENGINES, AND TEN TIMES THE POWER.

Not a Valve, Spring, Cam, Lever or Eccentric about them.

ARE NOT LIABLE TO GET OUT OF ORDER.

NO ENGINEER REQUIRED; A CHILD CAN RUN THEM.

Twenty to thirty pounds of coal will run a One Horse Engine ten hours, and will pump in same time TWENTY THOUSAND GALLONS FORTY TO FIFTY FEET HIGH.

They are well adapted for the use of Printers, Sausage Makers, Bakers, Machinists, Locksmiths, Chu ning, Sawing Wood, Bag Factories, Office and Spice Mills, etc.

Send for Circular and Price List, or call and see one in operation.

HUNTINGTON, HOPKINS & CO.,

Sole Agents for the Pacific Coast,

Junction of Bush & Market Sts., S. F.

Judson Standard Governor,

The BEST & MOST RELIABLE

IN USE.

Send for Circular and Price List to

H. P. GREGORY & CO.,

Sole Agents for Pacific Coast,

14 and 16 First street, - - San Francisco, Cal.

Giant Powder.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1,

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2,

For medium and sandy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

24v22-3m The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

ANGELL'S

CHARCOAL
DENTAL SOAP
for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

SMITH'S PATENT POWER MORTISERS.

WITH LATE IMPORTANT IMPROVEMENTS.

Mortiser.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements; and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new illustrated Catalogue. BERRY & LACE, Selling Agents.

Smith's Celebrated Moulders.

Cook's Patent Automatic Boiler Feeder & Regulator.

Economy in Operation. Absolute Safety from Explosion.

SIMPLER THAN A PUMP, AS IT REQUIRES NO ATTENTION.

ECONOMY IN FUEL.

Entirely Automatic, Reliable & Durable.

Cook's Automatic Boiler Feeders

WERE AWARDED THE HIGHEST PREMIUM OVER ALL MACHINES EXHIBITED AS BOILER FEEDERS AT THE GIN- OINNATI EXPOSITION AND THE ST. LOUIS FAIR.

The cuts show the operation of the Feeder. It was described in detail in the MINING AND SCIENTIFIC PRESS of May 20, 1876.

This Feeder will discharge from 40 to 200 gallons of water at one movement, where a pump would require hundreds of strokes to do the same work.

The water is kept exactly at the proper line, whether running fast or slow, without attention from the engineer.

Feeders, Heaters and Regulators Combined are made on this principle. Simple and economical.

The control of feeding water to the boiler, is taken out of the hands of the engineer and left, to unerring natural laws.

These Machines are now introduced on this coast for the first time, although they are extensively used in the Eastern States. They supply the boilers with great regularity, and keep the water at exactly the same level. As a protection against explosion they are simply perfect, leaving nothing to be desired.

ONE OF THESE FEEDERS CAN BE SEEN IN OPERATION AT THE PACIFIC IRON WORKS.

Address.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, JUNE 24, 1876.

VOLUME XXIII
Number 26.

Some of the Mines of El Dorado County.

[By our own Correspondent.—No. 4.]

Before leaving Placerville, curiosity led me to examine one or two more porphyry mines. Mr. Naper, at Poverty Point, is one of your lucky miners that seems to have been born under favorable auspices. With a clairvoyance that seldom errs, whenever he feels so inclined he goes down into one of his pockets and seldom returns empty-handed. Call it good luck, judgment, science, what not; some make it pan out well, while others can scarcely raise the color.

Such is life. I set out to describe his claim—but it was so much easier moralizing a little than puzzling my brain over his miniature quartz veins, that I have come to the conclusion since he has done so remarkably well and has such a good little claim, to jump it, and pass on to the next in order, that of

H. M. Hodge,

In the same neighborhood, which would in all probability astonish Sir Charles Lyell himself. It has some peculiarities not found in the books. It is the business of your correspondent to record the facts; let the geologist reason from them. The lode is about four feet in width; an open outcrop has been run into the hill, following the vein and of the same width, showing perpendicular slate walls on each side. Quartz veins six to ten inches wide out the porphyry, pitching north at an angle of 45 degrees, and extend across the lode from wall to wall instead of along the walls as in one formerly described. These veins are from three to four feet apart, the intermediate space being filled with porphyry. There is a thin vein of quartz, not more than one-eighth of an inch thick, that cuts the other veins and the porphyry, dipping south at an angle also of about 45 degrees. The best pay ore is usually found at the end of the veins, where they come in contact with the west wall. The singularity of the formation is sufficient apology for the minuteness of the description. It pays well.

Crossing the South fork of the American river to Kelsey, Spanish flat and Garden valley, a perfect nest of quartz claims was encountered, some of which ought to be noticed. The first visited was

The Chaparral,

On the brow of a hill in full view of the river, some three miles south of the St. Lawrence. It is now being prospected by Messrs. Condo, Dickson and Pondstone, some Amador county miners. They have an incline down on the vein upwards of 50 feet, and are taking out some fine looking ore. The character of the rock is improving as they sink, having a more bluish cast, and will probably mill \$15 per ton. It looks very promising.

The Big Chunk Quartz Claim

Is situated about one mile from Kelsey, at the head of Big Chunk ravine, which took its name from the fact that large pieces of quartz containing from \$3,000 to \$5,000 in gold were taken from it, resembling the rock from the ledge. Some of the ore at the shaft is of the blue ribbon character, which gives a fine prospect in the hand mortar, over \$3,000 having been taken out in this way in a single pocket. The owner of this property thought that the best rock would mill as high as \$30 or \$35 per ton, which did not seem improbable.

The Excelsior Mine,
On a parallel lode 200 feet distant, the property of Mr. C. F. Travis, of San Francisco, shows ore similar in many respects to that last mentioned. If I remember correctly three different lots of it were worked some time ago by Strong & Bro., metallurgists of your city, that yielded from \$8 to \$30 per ton. For the sake of my friend Travis I observed the ore and all the surroundings closely, and can see no reason why it may not be made to yield handsomely. It is a fine sulphuretted rock, some of the bluish cast and ribbon character, showing more or less free gold. It ought to be good milling ore.

Georgetown, El Dorado Co.

A Cheap Rock Breaker.

Mr. Charles H. Aaron's new book for practical miners, which is now going through the press and will be ready for distribution in a few weeks, contains many hints of great value which ordinary writers would probably overlook. He keeps cheap and simple mechanical devices for miners use prominently in view, and pays great attention to things by which the working miner without capital will be benefited. Among articles of this character described by him is a cheap rock breaker, a representation of which is given on this page.

BATHING POOLS FROM OVERFLOW OF GREAT HOT SPRINGS, YELLOWSTONE.

Bathing Pools of the Yellowstone.

The accompanying engraving shows another of those interesting scenes in the Yellowstone country, which Prof. Hayden has described so pleasantly in his "Geological Survey of the Territories." The scene in question represents a general view of the overflow of a great spring on Gardiner's river. In describing it Prof. Hayden says:

Before us was a hill 200 feet high, composed of the calcareous deposit of the hot springs, with a system of step-like terraces which would defy any description by words.

In the engraving, *a* is an inclined table made of one or more pieces of rock, enclosed by a low wall or rocks or wooden legs. On the table rests a mass of rock, *b*, which is connected by an iron rod, *c*, with the crank, *d*; another iron rod, *e*, also fastened into the rock,

A CHEAP ROCK BREAKER FOR MINERS' USE.

b, passes through a slot in the post, *f*. The ore to be broken is thrown upon the table in front of the moving rock, which, by the rotation of the crank in the direction of the arrow, is lifted and drawn forward over the ore. As the crank continues its rotation, the weight of the rock and the sliding movement imparted to it crush the ore beneath it and cause it gradually to work out at the lower end of the table, when it may be transferred to a pulverizing barrel, or sifted and the coarser part reground in the machine. This is merely a suggestion, and improvement will doubtless be made by intelligent miners.

The California building at the Centennial was opened Wednesday.

yards in diameter, and many of them going to decay. Here we find the largest, finest and most active spring of the group at the present time. The largest spring is very near the outer margin of the terrace and is 25 by 40 feet in diameter, the water so perfectly transparent that one can look down into the beautiful ultramarine depth to the bottom of the basin. The sides of the basin are ornamented with coral-like forms, with a great variety of shades. These springs have one or more centers of ebullition, and in this group it is constant, seldom rising more than two to four inches above the surface. From various portions of the rim the water flows out in moderate quantities over the sides of the hill. Whenever it gathers into a channel and flows quite swiftly,

basins with sides from two to eight feet high are formed, with the ornamental designs proportionately coarse, but when the water flows slowly, myriads of little basins are formed, one below the other, with a kind of irregular system, as it might be called, which constitutes the difference between the works of nature and the works of art. The water holds a great amount of lime in solution. It also contains some soda, alumina and magnesia. The ebullition is largely due to the emission of large quantities of carbonic acid gas. As the waters flow down the sides of the mountain, they constantly deposit more or less of this calcareous sediment in almost every possible variety of form. Underneath the sides of many of these pools are rows of stalactites of all sizes, many of them exquisitely ornamented, formed by the dripping of the water over the margins of the basins.

Dissatisfied Stockholders.

Dissatisfied stockholders seem to be more common now-a-days than satisfied ones, but we are glad to see that in numerous instances the investigations which have taken place have been productive of benefit, and those charged with corrupt practices and mismanagement have been deposed from office.

Among the latest companies undergoing a sort of investigation are the South Chariot and the Newark. The South Chariot stockholders held a meeting last Saturday, and during their proceedings the Board of Trustees made a virtue of the necessity and stepped down and out, handing in their resignations. Three of these were accepted, and Joseph Naphtaly, L. Steinbert and Mr. Perin elected in their stead. Minar and Kannally, of the old board, were retained. Joseph Naphtaly was afterward elected President, and the Secretary and Superintendent were re-elected. The first proceeding was to save \$150 a month by cutting off the President's salary. He will receive glory and thanks for his services in the future. Other reductions will be made. It was decided not to interfere with the assessment now levied, as the company is in debt, and the new powers intend to start a new balance sheet.

The dissatisfied Newark stockholders also held a meeting on Saturday. The *Chronicle* says it was stated that the President received \$100 per month; Superintendent, \$400; Foreman, \$250; Secretary, \$200. All these items appear on the books, with \$25 for miscellaneous purposes. The Committee found on the books a charge of \$50 for moving the office. The "office" consisted of "six little books and one little box"—not one dray-load. Three horses are charged with \$50 worth of grain per month. The books are in such a condition that nothing can be made out from them. It was stated that the mill was doing outside work, no ore being taken from the mine, and running behind \$1,000 each month. Joseph Naphtaly related how the South Chariots had accomplished their ends, and stated that as the company was incorporated before the alteration in the Code, January 1st, 1873, only a majority of the stock need be represented, whereas if it had been incorporated after that date, it would require two-thirds of the stock. About 7,000 out of the 18,000 shares represented in the movement were turned in, and the meeting adjourned.

REPORTS from British Columbia state that miners were pouring into Dease creek, and all the old companies are making preparations to work their claims. Provisions are scarce. Flour, \$35 per barrel. The new strike lately reported on McName creek proved to be a very small one. The miners who took up ground soon abandoned it. Deep diggings are reported struck on Thibet creek. The Stikine river is still high.

It is estimated that 6,000 men have gone into the San Juan country and Southeast Utah since March 1st, says the Salt Lake Tribune, and it is thought the number will be increased to fully 10,000 before the middle of October. The mines and good agricultural lands are the cause of this stampede.

FORTY-FOUR cargoes of coal have been shipped from Seattle to San Francisco since January 1st, 1876.

CORRESPONDENCE.

[Editorial Correspondence.]

The Centennial at Philadelphia.—No. 6.

In continuing our reference to the exhibits in machinery hall we come now to
The Dominion of Canada.

Although this exhibit appears somewhat contracted on the diagram, it is nevertheless quite extensive, interesting and creditable, and is eminently suggestive of the region whence it comes. An array of boats and fishing tackle forms a prominent feature. Nova Scotia sends a small prospecting quartz mill, much after the "Stockton" pattern, as emblematic of a very important feature in her industry—that of mining. It is the only exhibit of the kind, save the Nevada mill, on the grounds. There is also a magnetic separator, for separating magnetic sands from those not magnetic. It is used in the separation of the titanic iron sands of Canada for metallurgical purposes, and might be successfully employed by the large placer mining companies in California in separating the heavy magnetic black sands from the lighter ones, which may be afterwards more readily washed away from the gold by the pan or rifle. Several spark arresters attract attention here, and near them may be seen a number of portable hot blast forges, brick, tile and pipe machines, numerous specimens of bar iron, and an ingenious type setting and distributing machine, which, it is claimed, has a capacity of from 12,000 to 15,000 ems per hour from undistributed type.

Germany.

Now, turning to the left of the Canadian exhibit, we come upon the German department, the most conspicuous object in which is a huge monumental trophy, 28 feet high, built out of her peculiar ores of iron and their white, large crystal product of spiegel Eisen pig, broken into small pieces. The display is very fine and is not equaled by any other exhibit of the kind. This peculiar quality of iron contains from 12 to 15 per cent. of manganese. It is used for making the best quality of Bessemer steel, by mixing in small proportions with other irons.

Another interesting exhibit is a new atmospheric gas engine, exhibited by Langer & Otto, which appears to have obviated much of the impracticability hitherto connected with gas engines, particularly the heating of those parts directly exposed to the force of the explosion, and in taking the work off the piston in its rapid upward motion and confining it exclusively to the pressure of the atmosphere in forcing the piston down. In ordinary gas engines the force of the explosion is mostly converted into heat and thus lost for effective use, while at the same time it works great detriment to the machine. I shall not stop to further describe this novel motor at this time, as I have been promised a full illustration of the same at an early day, which I shall forward to the Press.

A very ingenious device, designed for turning a drill, worked by a rope, in deep well sinking, is also shown by a working model, but cannot be satisfactorily described without illustrations. It is well known that ropes are much more convenient for use in such work than iron or wooden rods, and would save more than half the expense of deep well sinking if they could be practically used. Several ingenious appliances have been devised with that end in view, but without success. This seems to accomplish what is desired, viz., to turn the rope and drill in regular intervals of space, so as to make a straight bore. It certainly works perfectly in the model, but how it acts in a deep well may be quite another thing. If it will do what is claimed for it in practice, it is well worth the attention of extensive well borers everywhere.

Krupp is also here with one of his 1,600-pounder guns and several small ones from his mammoth establishment at Essen. As I write workmen are engaged in making preparations to place the large gun just inside the main entrance to the machinery hall. The ordinary plank floor is being covered by square 10-inch timbers, on which a new floor will be laid to accommodate the monster.

The Exhibit from Belgium,

Which, it will be seen by reference to the diagram with our last letter, may be found on the north side of the hall, and just beyond the French exhibit, corresponding to its geographical position on the map. The most monstrous thing in this exhibit is a huge well borer, the design of T. Claudrus, a Belgian civil engineer, and employed for boring and tubing mining shafts and wells below the water level. This much he consists of an enormous gallows frame, supporting a leg of iron, shod at its lower extremities with a row ten feet long of movable chisels, used to stamp or drill holes into hard rock. This leg, with its long row of chisels, being caused to move up and down like a monstrous drill, and being rotated six inches after every stroke, soon works its way down into the rock, forming a well-like vein in diameter. After the chisels have done their work, a velvet bucket or a grappling iron is let down, which scoops up the mud or frag-

ments of rock, and brings them to the surface. If a larger well or shaft is wanted, the machine is further provided with another large forked leg, containing two and a half feet of chisels on each side, the blank space straddling the ten foot hole already made. When this is set to work it cuts around the previous well and enlarges it to 15 feet in diameter. It seems at first sight as though this machine was made merely to show how much of a possible monstrosity could be put into such huge shape; yet the agent states in his circular that these machines have done a large amount of work, at a much less cost than it could have been done in the ordinary way of drilling and blasting. Forty-four different shafts are enumerated, located in France, Great Britain, Belgium and Germany, which have been successfully sunk by these machines, varying in depth from 115 to 760 feet, and in diameter from 10 to 15 feet. A gigantic tubing apparatus accompanies this exhibit, by which heavy cast iron sections of tubes two inches thick and 15 feet in diameter can be readily adjusted in the deepest shafts. Lighter tubes may of course be used when the ground and depth will permit. It is possible, according to the above record, that one of these machines might prove useful in California or Nevada.

Belgium also exhibits a double Corliss engine, built at the company's works in Providence. It is really a splendid machine, and the reception of such an order from the government of a country so far advanced in the art of engine building as Belgium, is a high compliment paid to the Corliss company and to American mechanical skill. We also have here beautiful machines for working wool, cotton and iron; also, two very fine carriages—one a double seated open carriage, and the other a single seated covered one. We have also multitubular filters, rotary pumps, gears and punching machines. This little country, by her exhibit, both here and in the main building, gives evidence that she is really what she is said to be—a beehive of artisans, in which there is scarcely any important branch of industry neglected.

Sweden.

One of the principal exhibits made by Sweden is in Bessemer steel. It is shown only in part in the building. Locomotives and car wheels made of this steel are shown which are said to have run 190,000 miles without being turned, and still show very little wear. The ordinary life of a locomotive wheel is from 60,000 to 80,000 miles. Railroad axles and car wheels are exhibited in the various stages of their manufacture, so conditioned as to show the superiority of the iron from which they are made—bent, twisted and hammered together in a cold state; drawn cold into knots; worked cold by means of powerful pressure and percussion under the steam hammer, etc., all of which is designed to show the excellency of the Swedish iron and steel—which deservedly stands ahead of all other productions of the kind in the world. Machinery for making castings is also shown. This set consists of eight pieces, all neatly made and effective, but not equal to that shown by the United States in the Government building. Circular saws and gaug saws are also shown, to remind us that Sweden is a lumber as well as an iron producing country. A number of cooking stoves, ranges and heating furnaces are also shown. Among the cooking stoves is a "rotary," quite similar to those used in this country 25 years ago. Her sewing machines have already been noticed.

The only foreign built locomotive, aside from a small underground mining locomotive in the English section, is shown by Sweden. This is a tank machine and built to run in the mountains on a narrow gauge track. It is evidently a well constructed machine, and capable of doing good service, but of course will not come up in neatness of construction or compactness of build with a similar class of engines turned out by the Baldwin locomotive works. A large upright engine (Wolf's pattern) is also shown, also a horizontal engine of quite a different pattern, both well built and showing good work. A new and novel governor cut-off is shown, working by a cylindrical expansive valve, which appears to be a most excellent and effective device.

The Swedish exhibit which of all others from that country is the most attractive to the general public, is a full set of instruments—12 in number—designed to illustrate the "Swedish movement cure." It is exhibited by Dr. G. Zander, a native, who exhibits each piece of machinery in practical operation at certain hours of each day, submitting either his own person and limbs or those of any of the visitors who may be willing to try the virtues of the "movement cure."

Sweden also exhibits in agricultural hall, but her chief exhibition is in the main building, both of which will be noticed in due time. When it is recollected that this little country is not larger than California, and has no greater population than the State of New York, it is a matter of much gratification to American visitors that she has taken so great an interest in our Centennial exposition. Mr. C. Jablin, who is chief commissioner for Sweden, states that this exhibition greatly exceeds any previous similar efforts of that country at world's fairs. It may not be generally known that a large colony from Sweden, consisting of about 1,000 in number, landed at the mouth of the Delaware river as early as 1638, and there founded "New Sweden." Many of the present citizens of Wilmington, Philadelphia, and other places in this vicinity are proud to trace their ancestry back to this settlement, and some of them keep

their peculiar church organizations to the present day.

The Spanish Exhibit

Is scarcely presentable as yet. The chief effort of this country has been made in other departments than that of machinery. The principal article thus far visible in machinery hall is what appears to be a small chain excavator, with an engine to drive it. Another small engine is also shown, and a sewing machine, much after the style of the American machines, and handsomely mounted on a somewhat imposing pedestal. There is also a model of a railroad track of peculiar construction, the particular application of which is not apparent and cannot be made so to the uninitiated in the absence of any attendant.

Although the Spanish exhibit in this hall is quite meager and very limited in extent in comparison with the more pretentious exhibits around them, we cannot but admire the courage of the three or four individuals who are here. They appear in no way set back by the disparity, and work on with as much nonchalance as though there were scores of their countrymen present. A most excellent spirit in this direction prevails everywhere. While each is doing his or her best to make the most of what they have, either as individuals or nationalities, every one seems cordial toward all around, and each seems to be striving to make the most of the exhibition as a united whole. The visitors also seem to be animated with the same spirit, and a complimentary remark is often dropped within the hearing of a minor exhibitor, which is evidently intended more as a word of cheer and comfort than for the real expression of an opinion in regard to any particular excellency or superiority of exhibits. It is gratifying to this witness and record such evidences of genuine politeness on the part of a people not over particular in such regards when acting as entertainers of those who are proverbial for such delicate attentions. It is such little things that will really accomplish the earnest results in making this great social and industrial reunion of the nations one of unalloyed pleasure and profit to all. It is by such means that whatever of rivalry may and should appear shall be so toned that even the defeated shall enjoy the successful competition of a neighbor almost equally with his own, consoling himself that what he has lost in point of honor will be more than made up by the ideas which he has gained in regard to a new departure, which he hopes will lead him to a sure victory in the next contest.

Spain's best efforts at this exposition seem to have been directed to the art gallery, to her general exhibit in the main building and in agricultural hall, where we shall find her in some future letter, holding a most honorable position among the leading nations of the world.

The Empire of Brazil.

The presence of the distinguished head of this government, and the interest which he has manifested in everything connected with the exhibition and with the resources of our country at large, attracts unusual interest to the Brazilian exhibit. Her display in the three principal buildings is all very superior, both in merit and in the manner and taste displayed in arranging the same. The two great nations—Brazil and the United States—occupy a very large portion of the American continent, and contain about one-half of its population. And, notwithstanding their dissimilarity in government and language, they are in many respects very similar, and in sympathy drawn very closely together. The commercial relations between the two countries are very important, and their diplomatic relations have ever been of the most friendly character. The interchange of products between the two countries is growing more and more important every year, and from conversation with her representative in charge at the exposition—Luis de Rezende—I learn that the people and government of that country are exceedingly anxious to still more encourage and foster this condition of things. It is to that end that this fine display has been prepared, which will enable our people to learn much about that country that they have never known before, and which they cannot gather from books. Let them go into the various buildings and see what Brazil is presenting for the world's gratification and for our mutual profit. Those who visit the exposition for study will find much to learn there. Our government and people have given Dom Pedro II a most cordial welcome as the great and enlightened ruler of a vast and productive country, which furnishes a rare instance of wise and progressive imperialism. They have also learned from the personal appearance of the Emperor how little of the common trappings of royalty hedge about an emperor when both ruler and people are enlightened and infused with modern progressive ideas.

Referring to the exhibit in machinery hall, we find a vertical twin steam engine, built at Rio Janeiro, and models of several other engines, evidently intended for river boats on the Amazon and the other great rivers of the empire, together with many other products of the shops of that country, which attest the skill to which her mechanics have arrived in the difficult art of forging, founding and working iron, steel and bronze. Two large eight-inch breech loading bronze siege mortars, elegantly finished, and two bronze ship's guns, one with a wooden and the other with an iron carriage, are exhibited, to which are attached all the modern appliances for working the same; also several pieces of field artillery of steel and bronze, rifled and breech loaders—all the works of native artisans—display much skill in the art of

cannon founding. A mountain four-pound howitzer of peculiar construction and mounted upon two horses—life size models—with a still more peculiar harness equipment, intended for mountain warfare, show that this people are earnestly studying the art of war—for protection at least. This mountain howitzer equipment is quite novel, and appears to be perfectly practical and simple in all its details. It is capable of great celerity of movement and most effective execution with properly trained horses. Perhaps our own government might learn something to its advantage from this exhibit in its contests with the Indians of our own mountain fastnesses. A miniature fort, with its armament and military surroundings, taken in connection with the more formidable displays already noticed, is eminently suggestive of the progress which Brazil is making towards an important position among the great nations of the earth.

But her most interesting and creditable display is in the arts of peace. A neat little pavilion, attractive with gay trappings of silk and woolen, is constantly filled with an admiring crowd of ladies and their escorts to witness an exhibit of the silk interest of that country, particularly in its productive department. The progress of the work is shown up to the production of the raw material, which is wound off from the cocoons with deft and fairy fingers, supplemented with very simple but effective machinery, the invention of Luis de Rezende, the gentleman already mentioned as in charge of the Brazilian exhibit, who is largely engaged in producing silk. This exhibit, together with the extensive ones in the main building and in agricultural hall, are highly creditable, and give unmistakable evidence of the rapid advance which this empire is making towards an important position among the leading industrial nations of the earth. As a further evidence of progress in this direction, we may allude to the fact that Brazil is fast binding together the distant parts of her vast empire by means of railroads across her great plains, and lines of steamboats along her magnificent rivers and throughout the immense extent of her sea coast. One of the finest locomotives on exhibition bears this description—"Estrada de Ferro de Dom Pedro." It is numbered "89," and was built at the Baldwin locomotive works, near this city, the Brazilians not having yet essayed the difficult mechanical branch of locomotive building. Mr. Williams, one of the proprietors of the works named, informed me that the figures 89 represented the total number of locomotives which his company had built for only one of the dozen or more different railroads now in operation in that country, that one, however, the most extensive of all.

Russia.

Owing to diplomatic difficulties Russia was the last European country that accepted the invitation to participate in our Centennial; consequently her preparations were made somewhat hastily. Moreover her goods were unfortunately sent on a ship which had to put back by reason of stress of weather. But for these circumstances she would have been all ready with her exhibits at the start. Her people manifest much energy, are good workers, and appear to enter with hearty zest into this great industrial contest. She has uncovered a number of locomotive tires, the special character of which is not apparent, unless it consists in their very great diameter—fully six feet or more. There is still in this department a large number of unopened boxes, whose contents are unknown to the writer, but which in due time will, no doubt, make a most interesting and creditable exhibition. We may take occasion to refer to them further when we come again to Russia in the main and agricultural buildings.

No other European nations except England, to which my next letter will be especially devoted, are making any noticeable exhibits in machinery hall.

W. B. E.

CARE OF LOOKING-GLASSES, ETC.—A correspondent of the *New England Farmer* says: "Perhaps some readers have wondered why looking-glasses sometimes get so dull and dim that no washing or rubbing will make them clear. That dimness is caused by heat. A looking-glass or mirror subjected to sunshine several hours every day, or to the hot air from a furnace, register, or stove, or to the heat of a gas light or kerosene lamp, will soon become ruined. At first some portion of the glass looks dim and misty, then more cloudy, and finally, spotted or speckled with black; for the heat has caused the coating of quicksilver to expand and loosen its hold upon the back of the glass, till, after a time, particles fall entirely away, and the glass, once beautiful by fair reflections, is rendered unsightly and unattractive forever. Oil paintings are often seriously injured by the same cause. Much of the blame laid upon the careless mixing of the colors—especially those used by modern artists—rightly belongs to those who hang the pictures. Care is taken to place them 'in good light,' still greater pains should be taken to secure them from heat. If, during some portion of the day, the sun shines directly upon these paintings, or heat rises constantly toward them from stove or furnace, the canvas gradually takes on a dull appearance and soon presents an array of cracks that fills us with dismay."

ALBUMEN.—No albumen manufactured is equal to that obtained from an egg, hence the incredible number of eggs consumed in the manufacture of calicoes. One of the large calico manufacturers in France is said to consume the product of 300,000 hens.

MECHANICAL PROGRESS.

Great Guns.

One round with the 81-ton gun, says *Iron*, was fired on Wednesday at the butts in Plumstead marshes. The charge consisted of 260 pounds of powder, and the result showed an increase of velocity in the projectile, with a diminution of pressure in the gun as compared with previous trials. This is the first time the gun has been fired with the enlarged powder chamber, and so far as can be judged at present, it appears that the alteration which has been made is conducive to the power of the gun. Sir Joseph Whitworth's new steel gun, with hexagonal bore, has come to grief. The experiments were made at the French Government butts at Gavre, and their main object was to show that, with a heavier projectile than that used with the Woolwich 35-ton wrought iron gun a higher velocity, and as a consequence a greater penetrative power, could be obtained by the new weapon. The projectile used on the occasion was about four times the length of its diameter, which, as the bore of the gun in its maximum caliber is 12 inches, would give it a measurement of about four feet. It was a shell, unfilled, and weighed no less than 1,250 pounds, or 50 pounds more than the bolt fired by the Woolwich infant, a gun of the same weight. The mild powders which are found to produce such satisfactory results with the wrought iron guns were first tried, but the velocities attained were disappointing, and the old description of powders, which are more violent in their action, were then resorted to. The velocity, however, was registered at 329 meters only, or about 1,080 feet per second, and ultimately the gun broke down under the enormous strain. The inner steel tube cracked for about three feet near the muzzle, and the metal of the powder chamber was found to have expanded to the extent of one-twelfth of an inch. One or more of the shells broke up in the gun.

A SUCCESSFUL SMOKE CONSUMER.—The *Pittsburg Chronicle* says: There has recently been introduced in Zag's Sable iron mills a smoke-consuming apparatus which certainly accomplishes all that can be desired. It would be hard to conceive anything more simple in its construction or operation. A one-half inch steam pipe runs along the forward wall of the furnace, some 20 inches above the grate bars. From this transverse pipe project inwardly a number of short pipes, terminating in a small orifice. Each of these is surrounded by a "sleeve" of larger pipe, one and one-quarter inches in diameter. The annular space between the interior of the larger and the exterior of the smaller pipes communicate with a flue opening with the outer air the side of the furnace. When a pressure of 20 pounds per square inch has been attained, steam is turned into the smaller pipe. Its escape from the orifice acts upon the air-filled annular space, much as the steam in the Giffard injector does upon the feed water, and, drawing it rapidly through the pipe, projects air and steam into the furnace. The heat of the fire decomposes the steam, and at the same time the carbon-laden smoke is utterly consumed and converted into a bright clear flame that lights up the interior of the furnace. This operation is observable through a mica door in the rear of the furnace. Fixing the eye on the top of the smoke stack, and noting the moment when the steam is turned into the consumer, the inky torrent of smoke is first seen rolling skyward. With the hiss of the escaping steam these clouds are dissipated, like the fog before the sun, and in a few seconds only a faintly depicted vapor is wreathing upward from the stack. The engineer states that the decrease in consumption of fuel amounts to 20 per cent. since the introduction of the consumer. The boilers are of the Wigand pattern. Clearly the days of the "Smoky City," as such, are numbered.

GOOD JOINTS.—Professor Rankin sums up the principles which should be adhered to in designing joints and fastenings in carpentry, concisely as follows: First, to cut the joints and arrange the fastenings so as to weaken the pieces of timber they connect as little as possible. Second, to place each abutting surface in joint as nearly as possible perpendicular to the pressure which it has to transmit. Third, to proportion the area of each surface to the pressure which it has to bear, so that the timber may be safe against injury under the heaviest load that occurs in practice; and to form and fit every pair of such surfaces accurately, in order to distribute the stress uniformly. Fourth, to proportion the fastenings so that they may be of equal strength with the pieces which they connect. Fifth, to place the fastenings in each piece of timber so that there shall be sufficient resistance to the giving way of the joint by the fastenings shearing or crushing their way through the timber.

PRODUCTION OF PIG IRON IN 1875.—The *Bulletin* of the Iron and Steel Institute gives the latest available statistics concerning the production of pig iron in this country: The production of pig iron in 1875 was 2,666,581 net tons, against 2,689,413 tons in 1874, 2,868,278 tons in 1873, and 2,854,558 tons in 1872. The decrease in 1875, as compared with 1874, was 422,832 tons, or more than 15 per cent. The following States, however, increased their production in 1875 over 1874: Maine, Virginia, Geor-

gia, Indiana, Illinois and Wisconsin. The decrease was all in anthracite and charcoal pig iron, respectively 294,098 and 165,567 tons; while there was an increase in the production of bituminous coal and coke pig iron of 36,833 tons; the net decrease being as stated, 422,832 tons. The number of completed furnace stocks at the close of 1875, not including abandoned stacks, was 713, against 693 at the close of 1874, 657 at the close of 1873, and 612 at the close of 1872. The number of stacks added to the productive capacity of the country in 1875 was, therefore, 20, against 36 in 1874 and 45 in 1873. These figures, however, do not represent the whole number of new stacks built in these years, as some furnaces were abandoned in each year. The exact number of new furnaces completed in 1875 was 24, against 38 in 1874, 50 in 1873, and 41 in 1872. Of 713 completed stacks at the close of 1875, 293 were in blast and 420 were out of blast.

A MECHANICAL SCISSORS MAKER.—The *Sheffield Telegraph* says that, "Mr. Henry Walker, manager, 72 Napier street, Sheffield, has obtained provisional protection for an invention which will excite considerable interest in the scissors trade. He has discovered a means of entirely dispensing with skilled labor in the production of scissors blades. At present, as our readers are aware, the process of forging is one requiring considerable skill and time. Mr. Walker, by an adoption of existing machinery, completes the operation of making scissors blades from the sheet of steel, by the aid of a boy or girl. The blank is 'fired,' the hoot cut, and the blade shaped, without the intervention of a skilled hand, at twenty times the speed at which they are at present produced by hand forging. Samples of machine-made blades have been supplied to leading scissors manufacturers, who have found them to answer admirably. Mr. Walker is at present in treaty with the scissors manufacturers' association, to whom the discovery must at present be exceptionally important, seeing that the scissors forgers are on strike."

FINE WORK.—The *Scranton Republican* says: One of the most ingenious pieces of mechanism we have seen in some time has just been completed by two Scranton mechanics, W. Y. Thomas and George Pettigrew, at their home in this city. It is a model coal mine and breaker in miniature, showing, on a small scale, but with an accuracy really marvelous, the *modus operandi* of mining coal and putting it through the several processes which it undergoes in preparing it for market. The entire machine is actuated by steam, setting miners, mules, breaker machinery, cracker-boys and cracker-boxes to work, and reproducing in a wonderfully realistic manner and at a glance, the busy scenes witnessed at any of our coal mines in full operation. The machine stands nine feet high to the top of the breaker tower, five feet six inches wide across the chutes, six feet six inches wide across the mine, and fourteen feet long.

SCIENTIFIC PROGRESS.

Another New Explosive—Herakline.

The *London Mining Journal* says that another new explosive—herakline, which is an improved quality of diorrexine, a blasting powder in considerable favor among the miners of Austro-Hungary—is being brought forward; and as very gratifying certificates of its efficiency and cheapness have been given by prominent French mining engineers, it is probable that the material will meet with a favorable reception in this country. The patent by which the invention is secured are not yet sufficiently advanced to permit of the details of constituents of the powder and process of manufacture being published, but an early opportunity will be taken to make all these particulars known. In the meantime it may be stated that in its present form, although it is so safe that in Austro-Hungary its manufacture and transport by railway is permitted almost without restriction, it is claimed to possess considerable advantages over the powders ordinarily used, especially when applied in hard and compact rocks. The weight of herakline is at least 30 per cent. less than that of ordinary gunpowder, yet the same volume produces a more powerful effect; whilst the price, in Austria, being at least 15 per cent. lower than that of ordinary blasting-powder, it follows that a saving of 45 per cent. is effected by its adoption.

The composition of herakline is stated to be such that its explosion cannot be effected either by heavy blows or by friction of any kind; indeed, it will not explode until brought into contact with a blaze of fire, and then only when deposited in a hermetically closed space. No particular manipulation is necessary in employing it. This explosive is generally used in the form of meal or flour—granulated or not. The loading of a mine with herakline is effected precisely in the same way as the loading with ordinary gunpowder; but it is requisite to ram the charge tightly into the boring-hole. The explosion is then easily and easily effected, either by electricity or with an ordinary fuse. The process of charging, or even the withdrawal of the charge in case of misfire, is said to be positively free from danger; and considering the relative safety of herakline and dyn-

amite, it is remarked that in order to appreciate the advantages accruing from the use of herakline in comparison with the employment of dynamite, the vast importance of the entire innocuousness of the former must, above all, be fully considered. Moreover, a very great difference in the cost price of these two explosives is well worthy of being taken into account. Dynamite No. 1, hitherto highly approved of for all blasting purposes in large mines and quarries (composed of granite or other hard stone), is at least three times dearer than herakline.

Germination of Seed in Cold.

It is a general belief that plant seeds do not germinate at a temperature lower than 40 degs., but late experiments made by Uloth, and published in the *Flora*, a German botanical magazine, show this notion to be erroneous. Dr. Uloth experimented on the seeds of the maple, (*Acer platanoides*), and of *Triticum*, which germinated at 32 degs. In the winters of 1871-2, and of 1872-3, he experimented as follows: he took two boxes and in each had a certain depth of water frozen into a block of ice. In these blocks he made furrows four millimeters (.004 of a meter 39.371 of an inch in English measure) deep, in which he sowed seeds of various plants which were the same for two boxes. He then covered the boxes with a plate of ice, and put them away in two ice houses. He then partly filled two boxes with soil, in which he sowed the same kinds of seeds. These boxes he also covered with plates of ice, and put them in the same ice houses with the others. Care was taken to have a good thickness of ice (over four feet), surrounding the boxes on all sides, so as to provide against any elevation of temperature. The boxes were placed in the ice-houses in January, 1872, at a temperature of 40 degs., and they were taken out on May 15th. In 1873 they were placed in the ice-houses in February, the temperature being 37 degs., were examined on March 25th, and removed on May 15th. The kinds of seed sown were 25 in number. On March 25th, four had germinated, viz: *Lipidium ruderalis*, *L. sativum*, *Sinapis alba*, and *Brassica napus*, all cruciferae. On May 15th, besides the foregoing, the following seeds had germinated: *Arabis alpina*, *Elthionema saxatile*, *Brassica nigra*, *Petroselinum sativum*, *Cannabis sativa*, *Ervum lens*, *Pisum sativum*, *Avena sativa*, *Secale cereale*, *Hordeum vulgare*, *Triticum vulgare*. Hence, the seeds of cruciferae and of gramineae fully germinated at the temperature of 32 degs. Of the seeds named about an equal number vegetated in the ice and in the earth. The radicles had penetrated the blocks of ice. The seed which had not germinated lay rotten on the surface of the ice or of the soil.

THE MILLEPORA A TRUE CORAL.—The animal of the coral, millepora, was by the late Professor Agassiz regarded as a hydroid polyp, or jelly-fish, rather than a true coral polyp. Now, however, it has been shown by Mr. Mosely, of the *Challenger* expedition, who studied the millepora at Bermuda, that the animal is a true polyp. He says that the examination of the millepora is beset with serious difficulties; but he observed that there are large and small polyps, that both kinds have tentacles and appear to be four in number and to be compound. Before this, however, Gen. Nelson, of Bermuda, had made drawings of the animal of millepora, upon which the following comments have been made by Prof. Duncen, of London, in *Nature*: "It is a satisfaction for me to be able to state that Gen. Nelson's drawings prove that Agassiz saw a part of the polyp, and that Mr. Mosely's beautiful delineations, far in advance of all, testify to the correctness of my fellow-worker. I do not credit the hydroid nature of the polyp now, any more than I did when writing the reports on the British fossil corals, and I believe millepora to be an actinozoan."

THE MICROSCOPE AS A CHEMICAL TOOL.—How useful the microscope may be to investigate the composition of solutions of metallic salts, may be illustrated by the following easily-produced exhibition of crystal formation. Upon a slip of glass place a drop of liquid chloride of gold or nitrate of silver, with a particle of zinc in the gold and copper in the silver; a growth of exquisite gold or silver feras will spring up under the eye. It is also interesting to watch under the microscope the evaporation of a drop of any salt solution, especially with polarized light, when the play of various colors, continually changing with the increasing thickness of the delicate crystals, is not only delightful but instructive. Further, it is instructive as well as interesting to watch the action when a drop of the solution to be investigated is placed under the microscope next to a drop of the reagent, and brought in contact while watching the results.

SCIENCE UTILIZED IN COURT.—Science was successfully brought to bear in a forgery suit in court ten days ago in New York, where the testimony of experts and other witnesses failed. It was in the progress of a suit for the recovery of the amount of a check for some \$63,000, purporting to have been certified by a bank teller, but the certification of which was claimed to have been a forgery. The magic lantern and spectroscopic settled the matter. A photographic artist, having darkened the court-room for the purpose, produced on the wall a large picture of the certified check, and pronounced it to be genuine on comparing it with similar certificates acknowledged to be in the handwriting of the teller.

USEFUL INFORMATION.

A Cheap Refrigerator.

It is thus described in the *Country Gentleman*: "It is about the size of and resembles, on the outside, an ordinary tool chest; within there are pieces of wood fastened on for supports, and a lining of zinc put in, the space between the zinc and the wood being filled with pounded charcoal. This filling must be all around, in the cover as well as in the bottom and sides. In the ends of the box, cleats of zinc are soldered on, and the shelves of perforated zinc, or wire, or of wooden slats are slipped in. For a rack to put the ice on, take four slats about four inches long and nail them firmly to a little block or plank; set this block down (like an inverted kitchen table) in a basin, and put it in the middle space in the box, between the rows of shelves. To make a piece of ice do the greatest amount of service and last the longest possible time, wrap it closely in several thicknesses of flannel and lay it on the rack. A square tank holding a pail or two of water can be made of tin or zinc and fitted close up to the inside, with a pipe leading through the box, near the bottom, and a faucet attached. If this is kept filled with cold spring or well water, and a lump of ice thrown in occasionally, it will be found a desirable convenience in hot weather. After the box is finished it should be painted and set where the cover, when lifted up, can rest back upon a brace or frame, as it is heavy and would easily break from the hinges. A cellar is a good place for the ice box, but it may be kept in the pantry, store-room or wood-shed, as is most convenient."

We may add that, if kept in a cool cellar, a rough wooden chest, without the zinc lining and the charcoal, will make a very tolerable refrigerator, if the ice is well wrapped in flannel as suggested above.

MOths IN CARPETS.—Moths will work in carpets in rooms that are kept warm in winter as well as in summer. A sure method of removing the pests is to pour strong alum water on the floor to the distance of half a yard around the edges before laying the carpets. Then once or twice during the season sprinkle dry salt over the carpet before sweeping. Insects do not like salt, and sufficient adheres to the carpet to prevent them alighting upon it.

An Antwerp chemist has lately discovered that the vapor of chloroform will extinguish the flames of petroleum vapor very speedily, and destroy its explosive and combustible proportions, if mixed with it.

GOOD HEALTH.

CURE FOR POISON IVY.—A correspondent of the *Chronicle* writes: I wish to inform your readers of a dead sure cure for ivy poison, that is, those of your readers who attend ponies on week days, not the Sabbath-breakers, for them there cannot be too much ivy; I have carried it with me everywhere where I have ascertained there was the least danger. What is more common than lime? Take a piece as large as a walnut, unslaked; dissolve it in a seucer in a small quantity of water; wash the hands in it; apply to the parts affected; in fact, wash the face and neck, etc.—some of 'em know what etc. means before this—and I tell you there will be no inconvenience from that dose of ivy. I am very sensitive to the poison, so much so that if the wind should blow the dust from the ivy upon my person I am gone; but the lime always straightens me out. I hope you will find it convenient to give this a place in your columns—so simple a remedy and one that will afford immediate relief to those affected.

HOW TO CHECK COUGHS.—Dr. Brown-Séquard, in his late Boston lectures, says that there are many facts which show that morbid phenomena of respiration can always be stopped by the influence of arrest. Coughing, for instance, can be stopped by pressing on the nerves of the lip in the neighborhood of the nose. A pressure there may prevent a cough when it is beginning. Sneezing may be stopped by the same mechanism. Pressing in the neighborhood of the ear, right in front of the ear, may stop coughing. It is also preventive of hicough, but much less so than of sneezing or coughing. Pressing very hard on the top of the mouth inside is also a means of stopping coughing. And he adds that the will has immense power there. There was a French nurse who used to say, "The first patient who coughs here will be deprived of his food to-day." It was exceedingly rare that a patient coughed then.—*Baltimore Physician and Surgeon*.

SMALL-POX SPREAD BY DOGS.—A rural sanitary organization in England has applied through Dr. Mackintosh (*British Medical Journal*), for an order from the magistrate to have all dogs in the district of Boleover chained until small pox has disappeared in that locality. Dr. Mackintosh considers, and very properly, we think, "that the disease is spread from house to house more by domestic animals than by anything else." We believe that the more this subject is examined from this point of view the more the views advanced will be considered correct. It is possible also that the spread of other contagious diseases, such, for instance, as scarlet fever, may be explained in this way when all other recognized reasons have failed.—*Medical Record*.

Mining Share Market.

Mining stocks have been extremely dull of late and very much depressed in price. During the latter part of the week a slight improvement has been manifest; still there has been no special activity. Reports from the mines continue favorable and no particular reason is given for the present low market, which has been an unfortunate one for many. Our stock tables show the fluctuation for the week, and also the highest and lowest prices.

The San Francisco Board has resolved to adjourn from Friday, June 30th, till Wednesday, July 5th, at 12 m. No business to be transacted in the street. No definite action has yet been taken by members of the Pacific Exchange regarding the coming national holiday, but it is understood a large number are in favor of adjourning for even a longer period.

Considerable interest is being manifested by holders of Savage stock in the election of officers, which takes place about the middle of July. A large number express themselves as dissatisfied with the past year's management, its large expenditures and onerous assessments. The fear is quite general that the mine may share the same fate that has befallen the Gould & Curry, that is, be need as a drain for adjacent mines. It is said some action will be taken by large holders to secure a more brilliant future.

We give in another column the proceedings of the South Chariot and Newark companies at their recent investigation meetings.

The Overman company will hold a special meeting on July 25th, to take into consideration and decide upon the proposition to increase the capital stock of said company from \$3,840,000, divided into 38,400 shares of the par value of \$100 each, the present capital stock, to \$11,520,000 divided into 115,200 shares of the par value of \$100 each.

The Lady Franklin company also propose to increase the capital stock from \$100,000 in 2,000 shares of \$50 each, to \$10,000,000 in 100,000 shares of \$100 each.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

ADVANCE MINE.—Superintendent's Letter, June 19: The shaft is down 255 feet; the rock is still hard but more uniform. All the stringers are dipping with the ledge, showing that the ledge is strong enough to support the surrounding rock. The stringers show good ore.

BUTTE.

NEW DRIFT.—Oroville Mercury, June 16: We saw a contract drawn up last Tuesday for the construction of a short distance from town that bids fair to be of some importance to this place. It starts at the West branch, opposite Dogtown, and runs to Dry creek, two miles above Pence's ranch, being a distance of nine and a half miles. It is to carry 3,000 inches of water, and will be completed on or before the 15th of October. E. J. Davis, the owner of the Dry Creek claim, owns the ditch, and Chin Poo is to make it. He begins work immediately with 150 Chinamen. The cost will be about \$30,000. The ditch will then be brought to Davis' claim, near Thompson's flat. But this is an after consideration and may not take place this winter, though all expect it will be done.

GOLD BACKS.—Last Sunday morning, the Spring Valley company's Charokas sent down to San Francisco two golden bricks, valued at \$58,000. It was only a month ago that a similar lot was sent down. Gold enough has been taken out of that claim within the past year to buy all the products of some of the counties in this State.

IN THE FIELD.—Some time ago a number of gentlemen in Oroville, among whom are Hon. P. O. Hundley, Thomas Callow, T. C. Rogers and some four or five others, took up an extensive claim on the North fork of Feather river, and Mr. Callow and Mr. Zambelich left town Wednesday morning with civil engineer Reese, to make the preliminary survey. Just this side of Yankee hill the river makes a huge bend in the shape of a horseshoe. In going a distance of eleven miles, it comes back within three miles of the place where the bend begins. Now, by running a tunnel and ditch one mile, and turning the whole river into Blind canon, some 16 miles of the bed of the river can be rendered perfectly dry. To see if this can be done is the object of the present survey. The company will incorporate and sell stock sufficient to push the work on to completion. They have some able men in the company, upon whose judgment those not so well posted rely with the most implicit confidence.

CALAVERAS.

CLEAN-UP.—Calaveras Chronicle, June 17: Forty-six tons of rock from the Badlock mine at Mosquito was lately crushed in Garland's mill. The quartz paid \$80 per ton. Two shafts have been sunk on the mine, 75 feet deep, and a level driven connecting them. The ledge averages about three feet and a half in width and will all pay for crushing. The mine is undoubtedly a good one, but it is not supplied with machinery for working to advantage.

CONTRA COSTA.

COAL YIELD.—Contra Costa Gazette, June 17: From a well informed correspondent we learn that the April "out put" from the Black Diamond was the smallest in any month during the past four years, being a fraction more than 4,700 tons, and the product in May was 6,186 tons. The combined product of the Pittsburg and Union mines, at Somersville, for the month of May, was a fraction more than 4,569 tons, aggregating for the month, with that of the Black Diamond, 11,755 tons, the market value of which was \$65,000—quite a respectable sum after all, for dull times, though probably less than half as much as is realized when there is a moderately good demand for coal.

EL DORADO.

OLD HOKOYA.—Superintendent's Letter, June 19: Timbering of both shaft and main tunnel has been completed. One thousand tons will be shipped out and kept ready for the mill. The ore breast is looking as good as ever.

INYO.

OSO MINE.—Osos Mining News, June 17: The Defiance mine has opened up some wonderful lodes of ore since last week. The Defiance furnace have been running successfully the past week, making their usual large shipments of bullion.

LEE DISTRICT.—We learn from a very reliable source that the mines in Lee district, belonging to the Emigrant mining company, never looked better than at the present time. In the Cactus mine, at the bottom of the incline, at a depth of 60 feet there is a vein of seven feet of the high grade milling ore for which this mine is noted, the whole being free milling ore, entirely free from feed. The Valentine is looking splendidly. The ore in this vein is supposed at one time to have been entirely given out, but further explorations have demonstrated that a good vein of rich ore exists and is likely to continue to a good depth. The mill is all completed and will start the fore part of next week; and we predict that the most valuable shipment of bullion will be made that was ever sent from a five-stamp mill.

NEVADA.

TUNNEL COMPLETED.—Nevada Transcript, June 17: The Mifflin mining and water company have completed their French Corral tunnel to the upper shaft, a distance of 3,600 feet. This work has been under course of construction since the month of March, 1872. A portion of it was driven by single hand drills and gault powder, but for the past two years the company has been using the Ingersoll drill with great success, making from 80 to over 100 feet per month through very hard rock. Had the air compressors been of the greatest capacity, the progress would have been still more satisfactory to the company, as the power was not sufficient to propel both drills (two being used at the tunnel) at the same time, and the speed of the construction of a work of such a magnitude is the opinion of the manager of this work, that with a compressor with power to raise the air to 60 pounds, (equal to same power of steam), would be ample to drive two four inch cylinder drills to the utmost speed, and driving the drill hole in much less time, thereby facilitating the construction of the work as well as lessening the cost of the same. The completion of the tunnel opens ground on a channel sufficient to last for four years, and a portion of which has been and is being worked by mill process and paying over \$300 per month. The company have an abundance of water to wash the ground, and it is expected the proceeds will be ample to pay for the great expense incurred in running the tunnel and leaving a fat margin besides.

ALLISON RANCH FRANKLIN MINE.—Grass Valley Union, June 13: The new hoisting works of the Allison Ranch Franklin mine were started up on Monday last. The mine was located contemporaneously with the famous Allison Ranch mine, in the year 1853, being its first northern extension of 1,200 feet. It was prospecting to some extent at that time, but no systematic development was undertaken and it remained unworked until the fall of 1875, when the owners determined to thoroughly prospect it. As a preliminary operation 45 loads of rock were taken from the ground, the explorations not extending to a greater depth than 15 feet, and the yield was \$6,000. A result so encouraging determined the owners to open and develop the mine, and in December last they organized and incorporated the company under the above name, a capital stock of 25,200 shares at \$40 per share. The first regular work was done by commencing a large shaft, which is 11 by five and a half feet in the clear, constructed in the very best manner, of the best quality of timber, containing two trackways and an apartment for pump and ladder way. The erection of the hoisting works was commenced about April 25th, and was completed on Monday in order for business. The engine consists of a 40 horse-power pumping engine, and a 30 horse-power hoisting engine; also, double hoisting reels, each five feet in diameter. The main building is 26 by 74 feet in dimensions, two stories 32 feet high, and is to be supplemented by a boiler shed and dry house 20 by 74 feet. The officers of the company are: Edward W. Collins, of San Francisco, President; Martin Ford, Superintendent, and John Ford, Foreman, both of Grass Valley.

PLACER.

RISING SUN.—Placer Argus, June 17: The Rising Sun mining company are meeting with good success. The shaft is down 600 feet in good ore, and the prospect for the future out of all paying rock. The shaft is running steadily, crushing 120 tons of ore per week, running in value from \$20 to \$30 per ton.

GOLD RUN is full of business and improvement. The mine are prosperous and extensive improvements are projected. The Gold Run ditch and mining company, which has run a number of bedrock tunnels in this district, will continue to work their main tunnel the coming fall. The English company cleaned up a few days ago with satisfactory results.

LAKE NOGEE.—Dutch Flat Forum, June 15: Thos. Williams gave us a call last Monday and exhibited a specimen from his claim on Wilmet ravine, weighing 19 ozs. 2 pwt. He and his partner, Frank Eddings, have about 50 acres of ground at an average depth of about 25 feet, all of which prospects well for the standard. They have suspended mining for the season owing to lack of water, but say that plenty of water can be obtained by digging a ditch from Burnett's ravine, four miles distant. Capital could be profitably invested here by constructing a canal having a capacity to furnish sufficient water to work the ground, as they are willing to give one-half for that purpose.

LAKE LANTANA.—The Liberty Hill mine has just finished cleaning up with good results. They set off a blast of 80 kegs of powder on the 9th which did splendid work. They are now refitted and busy washing again. The Raymond claim has turned off to clean up.

LITTLE YAK MINING ITEMS.—The Empire mine is progressing rapidly since their last blast; the gravel is being washed out, and the shaft is being cleaned up. The claim is about to turn off to clean up. They expect good results. The Christmas Hill mine is working through their new tunnel to good advantage.

SANTA CLARA.

SOUTH ALMADEN QUICKSILVER MINE.—San Jose Mercury, June 20: Our reporter paid a visit to the South Almaden quicksilver mine yesterday. This property, which the owners consider very valuable, and the indications certainly bear them out in this opinion—is located on Silver creek, four miles south of Evergreen. On the hills, for a distance of at least a mile, rich croppings have been found, and at the base of the largest a tunnel has been commenced, which, it is expected, will pass a good body of paying rock. The work heretofore has been done mainly in the flat, where the discovery was first made. The rock averaged as well as that taken out at Almaden, and has thus far been put through the furnace in sufficient quantity to pay expenses. In order to raise funds for tunneling the hill and for still further prospecting, 10,000 shares of the stock are offered for sale at \$1 per share.

SONOMA.

LOCAL MINING NEWS.—Russian River Flag, June 16: The Excelsior quicksilver mining company, in the Inyo district, is working two shafts night and day; no ore is being taken out, but they are running a tunnel alongside of the vein to connect with the shaft, for the purpose of ventilation. After the connection is made, the work of taking out ore will commence. The furnace has been repaired and is now ready to begin the reduction of the forthcoming ore. Superintendent Parr has removed his family to the mine, in order that he may the better keep his increasing details under the closest care. The Missouri, in the Pine Flat region, is idle. The Rattlesnake is doing but little. The Oakland, under Superintendent Dennis, is working 50 men, and turning out much quicksilver. The Geyser is prospecting with six or seven men. Their furnace is

at present employed by Wm. Whitton, in reducing surface rock and boulders. It will soon be used by the Kenick to reduce ore which they are now hauling from their mine. The Kenick company are highly elated over present prospects, and are pushing ahead with about a dozen men under Superintendent Hopkins, running an incline to reach the ore bed at a lower point.

TULARE.

MINERAL KING.—Visa's Delta, June 16: Mr. Ford, recorder at Mineral King, and acting superintendent of the New England tunnel and mining company, has just returned from the mines. He reports an unusual amount of snow for this season of the year on all the leading high up from the valley. He thinks it will be as late as the first of July before work can be profitably commenced on these leads. The company, however, have not yet started on the tunnel of the Lower claim. This drift having been run 162 feet fast fall, and the hearings being known, they had little difficulty in gaining access to it beneath the snow.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill News, June 15: The pumps have been kept working water during the past week, without having exhausted the flow or permitting the resumption of work at the bottom of the main shaft. The water, however, is showing signs of a gradual decrease, so that it will not probably take much longer to get it well under control.

DEARBY.—The frame of the new hoisting works building, 40 by 46 feet in size, and 30 feet in height, is up, ready to be enclosed. The building is being erected large and commodious, in order to have plenty of room for new and large hoisting machinery whenever needed. Sinking the main shaft is making good progress.

BROOKS.—The new and more powerful pumping machinery is expected to arrive some time during the coming week. As soon as it reaches the mine work will be resumed, and it cannot be done before that time, as the flow of water continues too great for the present machinery to contend with successfully.

WARN.—Sinking the shaft is going ahead at the very rapid rate of five feet per day, or 35 to 40 feet per week. It is now down 165 feet, the bottom in good blasting ground. The foundation walls of the new building are being laid and the timbers framed for the boiler house and carpenter and blacksmith shops.

CHOWS POINT.—Daily yield, 150 tons of ore. The east prospecting drift on the 1600-ft level, running east of the ledge, has not yet developed any new or valuable features. The main south drift on the 1700 ft level is steadily advancing toward the Belcher line, but has not shown paying lodes of ore.

PURSEPT.—Since last week's report 19 feet have been added to the depth of the shaft, making it 321 feet deep in all. The Ingersoll drills and machinery operate excellently, and no increase of water interferes with the regular progress of the work.

OVERMAN.—The west drift on the 1250 ft level is rapidly advancing, the face in good blasting ground. The preparation of the pumping machinery for again commencing the sinking of the main shaft is going rapidly forward. Daily yield of ore, 30 tons.

UTAH.—Sinking the main shaft is making much better progress, as most of the water flowing down the shaft has been caught up at the 650-ft station, leaving the bottom comparatively dry. The sinking is being pushed ahead very energetically.

SENRA NEVADA.—Sinking the main shaft is going steadily ahead, the work is good, working ground. Work is progressing well at all points.

SILVER HILL.—Sinking the main incline shaft is going steadily ahead at the rate of two and a half feet per day, the pump still handling the water with the most perfect ease. The east drift on the 440 ft level is steadily advancing.

SUCOON.—Sinking the shaft has been suspended for the present, in order to put in more powerful and efficient pumping machinery.

CRULLA-POTOSI.—Daily yield, 120 tons of ore, the average assay value of which is \$32 per ton. Sinking the main incline is making good progress, also sinking the combination shaft is making favorable headway.

BEST AND BELCHER.—Everything in this mine is quietly awaiting the completion of the new pumping machinery of the Gould & Curry, nothing can be done on the deep levels until that is finished.

CONSOLIDATED VIRGINIA.—Daily yield, 500 tons of ore. The ore breasts show little or no change in any portion of the mine. The extraction of ore was considerably interfered with for two or three days past by some necessary repairs to the 1500-ft station and the main shaft below that point. The new shaft, however, has a pump and the extraction of ore at all points is progressing as usual. The supply of ore at the mills was amply sufficient to keep all going, so that there was no stoppage with that portion of the work. The east drift on the 1500 ft level is making good headway. The drift west from the O. & C. shaft to connect with the east drift on the 1500-ft level is advancing at a rate of about 10 feet per day, and is now at the foot of the mine of Nevada. During the past week it has penetrated a distance of 70 feet, or at the rate of 10 feet per day. The erection of the new 80-stamp crushing mill is going rapidly ahead. The erection of the amalgamating mill is also getting well under way. The foundations are about completed, the framework ready for erection and the machinery is being set all in place, and ready to be placed in position for use. On the 1700-ft level the north drift is advancing as rapidly as the great heat will permit.

CALIFORNIA.—Daily yield, 350 tons of ore, keeping the mills running up to their full working capacity. The ore breasts on the 1600-ft level are opening up splendidly. The cross cuts recently started to the westward are making good headway, and are advancing with constant change of interest. The main north drift, connecting with the Ophir on the 1400-ft level, is being thoroughly retimbered. The east and west cross-cuts now being run on the 1600 ft level are showing the ore body to be as rich, if not richer, than at any other point where it has yet been opened. Sinking the C. & O. shaft is going on without interruption, at the usual rate of speed. A considerable quantity of ore is being extracted through the Ophir shaft, and the yield of the mine will be considerably greater for the month of June than it has been for any one month since the commencement of the extraction of ore.

OPHIR.—Daily yield, 300 tons of ore. The ore breasts both north and south on the 1600-ft level are yielding a good supply of excellent ore, with every prospect of continuing or even increasing the amount for a long time to come. The north drift on the 1600-ft level is steadily advancing toward the Mexican ground. On the 1700-ft level the drifts and cross-cuts have been cleaned out and repaired ready for more active future operations. The north compartment of the 1700-ft level has been completed, and the shaft is now furnished with three fine working compartments, either of which is calculated to do a large amount of hoisting. Both the raising up and sinking of the main incline shaft below the 1300 ft level is making steady and favorable progress. The mine has not for years been in as fine a working condition as at present.

AMAZON.—The west shaft is going rapidly ahead. Three levels have been opened in this mine, the lowest being at a depth of 300 feet. The ledge from the surface down to that depth has been gradually widening and is encased in regular well defined clay walls of the best possible character. On the third level a winze has been sunk to a depth of 20 feet on a strike of quartz and low grade ore. The shaft is being driven out by a flood of water, and the sinking stopped. It is now the intention to sink the main shaft 100 feet deeper and then tap the water and open a new level.

HALE & NORRIS.—No faster or more perfect work of the kind was ever accomplished than is now being done in the erection of the new pumping machinery at

this mine. Everything is steadily advancing toward completion, and it will be but a very short time before all will be in readiness to steam up. The old pumps and bolts are being taken from the shaft, the stations are being enlarged and the new pumps and columns are being lowered into position, ready to connect and put into use as soon as the engines are ready to start up.

YELLOW JACKET.—The north winze on the 1940-ft level is down 89 feet below that level, the bottom in good sinking ground. Cross-cut No. 2 on the 1910-ft level is in a distance of 220 feet, the face in very favorable formation. A drift has been started at a point 50 feet below the 1940-ft level in the east winze, which is now in 25 feet, the face in fair grade ore. On the 1740-ft level the east cross-cut between the north and south winzes is in a distance of 168 feet.

JULIA.—The main south drift on the 1000-ft level is rapidly advancing, the face in very favorable ground. The west drift on that level is also steadily advancing, the face in quartz and low grade ore of a fine and encouraging character. The face of the main south drift on the 1800-ft level is still in quartz and low grade ore of a better character than has before been encountered in that portion of the mine. The west drift on the same level is also showing fine quartz and low grade ore.

BULLION.—The progress of the northeast drift on the 2000-ft level has been greatly impeded during the past week by the breakage of the Imperial pumps. This trouble will, however, be remedied in a day or so more, and the work can then be forced as usual. The upraise from the 1700-ft level, and the winze from the 1400-ft level to meet it, are each making the usual fair rate of progress. Sinking the main incline is going rapidly ahead. The north drift on the 1400-ft level is also making excellent progress.

SAVAGE.—The foundations for the immense pumping engine are finished with the exception of placing the coping stone, which is now being done. The engine arrived yesterday morning and will be placed in position for work in a very few days. It will not now take a very great length of time to complete the whole ready to commence the extraction of water.

BELOCHEN.—Daily yield, 400 tons of ore. There is little change in any of the ore breasts or stops. The erection of the new pumping machinery is going steadily ahead. Nearly all of the machinery is now on the ground, and the foundations for its reception are fast approaching completion. Sinking the air shaft is making good progress. It is now down 50 feet below the 1600 ft level.

GOULD & CURRY.—Preparation for the erection of the new pumping machinery is being advanced as rapidly as the nature of the work will permit. The engine furnishing the steam power to drive the new section mill for the ventilation of the lower levels of the mine are up, and the erection of the other portions of the machinery well advanced.

NORTH CONSOLIDATED VIRGINIA.—Sinking the shaft has been suspended at the depth of 550 feet, pending the putting in of new and powerful pumping machinery. The foundations for the pumping engine and other machinery are being laid. Stations are also being cut in the shaft for the pump bolts and pumps.

IMPERIAL.—In the bottom of the north winze, on the 2000-ft level, during the fore part of the week, a few streaks of porphyry and poor ore was encountered, but yesterday afternoon the bottom was again in ore of the richest character, the average assays running up to \$400 per ton.

COSMOPOLITAN.—The fine circulation of air secured by the completion of the upraise from the main adit tunnel to the surface is of incalculable value in assisting the development of the mine. The distance to the surface, or length of this upraise, following the incline, is 154 feet, the vein in the shaft is steady throughout, and shows good widths of excellent ore at several points. The main drift, following the vein toward the northern boundary, is advancing steadily, with the face in fine grade ore.

JUSTICE.—Daily yield, 120 tons of ore. The ore breasts both above and below the 600-ft level look well, and yield a usual quantity of good milling ore. The main south drift on the 800-ft level is steadily advancing, the face in very favorable ledge material. The north drift on the 1000-ft level also shows better as the drift advances. Sinking the main incline is making good progress.

ROCK ISLAND.—The north drift on the 850-ft level still continues in a very favorable formation. The main west drift on the same level is showing quartz and spots of low grade ore. The main south drift on that level is also in quartz of a highly encouraging description. The main south drift on the 650-ft level is showing some fine quartz and low grade ore.

TWIN PEAKS.—During the past week the drift at the 75-ft level has been driven west a distance of 45 feet, penetrating what is now considered to be the main ore body. The drift is now at a distance of 180 feet from the Constock texture, and carries much more metal than any encountered heretofore in the mine. It runs due southeast and northwest, and shows a strong, permanent vein.

EMERALD.—The 600-ft station has been opened and a drift started to cut and prospect the ore vein on that level.

KOSUTH.—The opening up of the 500-ft level can now soon be commenced in good earnest, as the heavy flow of water recently struck in that portion of the mine is fast becoming drained.

BUTTE TUNNEL.—No increase of water, and work advancing finely in the header, the Ingersoll and Burleigh drills doing splendid execution. Total length of tunnel, 34.45 feet.

TAYLOR.—The new road has been completed to the site of the shaft. Sinking the shaft is going rapidly ahead, the rock in the bottom still blasting out finely.

GLACOW.—The combination shaft of the Amazon & Glasgow mines has attained a depth of 323 feet. The rock in the bottom is quite hard but blasts well.

ANDERSON.—The 800-ft level is being opened, and a pump tank at that point is being put in. Sinking will be resumed in about a week.

UNION CONSOLIDATED.—The prospecting drift north on the 1300-ft level is steadily advancing, the face still in very favorable ground. Otherwise nothing new.

SUPERIOR.—The new spur wheel arrived this morning and will be put in position ready to resume hoisting the water some time to-morrow.

Idaho.

WAGONTOWN MINES.—Idaho Avalanche, June 17: The 35 tons of Webster ore crushed at Leonard's mill only yielded \$22. It was quite a disappointment, as better returns were expected; but the fact that the ore was not assayed caused the disappointment. Even this yield assured us that it is a valuable mine when it can be worked economically.

POORMAN.—The recent developments in this mine have furnished material for encouragement. Samples of the rich rock taken on a few days ago which were assayed averaged \$25,000 to the ton in gold and \$3,000 in silver. This is one of the richest and most prolific developments that the camp has ever furnished.

GOLDEN CHARIOT.—The working force at this mine has been increased recently. The mill is running on first-rate quality ore, about 40 tons of which are daily conveyed from the mine.

MISCELLANEOUS.—There is a general feeling of hope that after the present storm of the court is over no obstacles being in the way towards taking steps looking to the resumption of work in the mines, matters will soon present a brighter outlook, and the mining situation steadily improve. Most of the stock of the Oro Fino is now controlled by men of capital and energy, and in connection with the assistance of recently arrived capitalists there are grounds for the belief that the mine will resume work at an early day.

HERCULES POWDER.

HERCULES Slaying the Giants.

Hercules, the son of Jupiter and Alcmene, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Eurystheus to execute a very great task, when he found himself opposed by several Giants, among whom were the powerful Giant Geryon, Eurystion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.
2. **UNIFORMITY.**—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.
3. **SAFETY.**—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.
4. **CARTRIDGES.**—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.
5. **ECONOMY.**—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. {Hercules X X No. 1, for extreme hard rock.
{Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself*:

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D., 1875.

Present—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court; Honorable Lorenzo Sawyer, Circuit Judge.

THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, Et AL., *In Equity, No. 1,237*—The Court having, on the 23d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., Solicitor for defendants, M. A. Watson, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered here dismissing said bill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

October 13th, 1875.

ENDORSED:—Filed and entered, October 18th, 1875.

(Signed)

LORENZO SAWYER,
U. S. Circuit, Judge Ninth Circuit.

L. S. B. SAWYER, Clerk.
By J. F. O'BRIEN, Dep. Clerk.

Sold by **THE CALIFORNIA POWDER WORKS, 314 California Street, San Francisco, Cal.**

Also, all grades of Black Powder, Fuse, Shot, Caps, Etc.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in one column one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, June 24, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Some of the Mines of El Dorado County; A Cheap Rock Breaker; Bathing Pools of the Yellowstone; Disastituted Stockholders, 401. A Word of Caution; End of Volume XXXII; The Mechanics' Institute Fair; How Valuable Mines Should be Recognized, Prospected and Worked; The Sutro Tunnel Decision, 403. Notices of Recent Patents; McCall's Road Grader, Ditch and Level Machine; Faulkner's Excelsior Family Fruit Drier; Patents and Inventions, 409.

ILLUSTRATIONS.—Bathing Pools from Overflow of Great Hot Springs, Yellowstone; A Cheap Rock Breaker for Miners' Use, 401. Faulkner's Excelsior Family Fruit Drier; McCall's Road Grader, 409.

CORRESPONDENCE.—The Centennial at Philadelphia, 402.

MECHANICAL PROGRESS.—Great Guns; A Successful Smoke Consumer; Good Joints; Production of Pig Iron in 1875; A Mechanical Scales; Maker; Fine Work, 403.

SCIENTIFIC PROGRESS.—Another New Explosive—Herkaline; Germination of Seed in Cold; The Millipede; A True Corn; The Microscope as a Scientific Tool; Science Utilized in Court, 403.

USEFUL INFORMATION.—A Cheap Refrigerator; Mothe in Carpets, 403.

MINING STOCK MARKET.—Sale at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 404.

MINING SUMMARY.—From various counties in California, Nevada and Idaho, 405.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 409 and other pages.

NEW ADVERTISEMENTS.

The Allen Engine Governor, Pacific Iron Works, S. F.; The Gardner Automatic Safety Stop Governor, Berry & Place, S. F.; Eleventh Annual Exhibition of the Mechanics' Institute, A. S. Halliday, Pres't, S. F.; Hope Quicksilver Mining Co.—Sale.

OUR INDEX, ETC.—We are unable to give this week as much reading matter as usual, on account of the index for the closing volume, which appears on the last page. This, with the crowded state of our advertising columns, has somewhat disarranged the usual order of things, and some of the advertisements appear on unusual pages. To make up for these deficiencies we propose next week to print a 24 page Centennial issue, with appropriate illustrations, and to publish moreover a very large edition. This, for the beginning of the volume, is an indication of the improvements we mean to make, as we propose to make the Press so valuable to its special class of readers that no one can afford to be without it.

NEW CANNEL COAL MINE.—This mine is situated three miles from Santa Rosa and half a mile from Smith's sulphur springs, Sonoma county. They have now sunk a shaft 40 feet in depth on an incline of 35 degrees, making it 24 feet in depth from the surface. The seam of coal is five feet wide complete, three of which is clean, good coal. They have saved the coal for the last eight feet. The coal husks clear and free, leaving but little white ash and no residue. We have received samples of the coal which appear to be of excellent quality. Our correspondent will soon visit the mine and send us a more detailed description of this new coal discovery.

A LARGE PAPER.—We acknowledge the receipt of the Centennial issue of the *Spirit of the Times*, probably the largest specimen of a newspaper ever published. The number is very profusely illustrated, and comprises 40 pages in all, much of it of a generally local character. The proprietors have shown a spirit of enterprise in keeping with the Centennial year and the name of their paper.

The Committee on Salaries of the Board of Education have recommended a reduction of five per cent. in teachers' salaries in this city.

A Word of Caution.

We occasionally hear complaints from the East of certain credulous persons having "taken in" by purchasing worthless mining stocks, supposing them to be of value. The general lack of knowledge in the Eastern States with regard to mining operations on this coast has led many unscrupulous persons who have been here to pass off on unsuspecting victims worthless mining stock, or persuading them by false representations to organize companies and advance money on worthless ground or ground which oftentimes has neither value nor locality. The latter used to be a favorite dodge, but the lead has been so closely worked that there is not much chance now for pay in it. But with mining stocks it is different. For the last year or two the Eastern papers have been filled with accounts of the bonanza mines and descriptions of bonanza millionaires. The various articles which have appeared on these subjects have caused considerable excitement wherever read. We know here what an excitement "the bonanza" raised among our own people who are used to mining excitements. We understand that the riches are confined to a few mines and that certain others stand a chance of coming in for their share; but nevertheless the people of this coast invested and continue to invest largely in other mines miles away from the bonanza, in hopes of striking it there, too.

If we who are supposed to be posted on these subjects have the stock fever so widely diffused we must not consider those unusually foolish who buy stocks of any kind which come along, with the expectation of making fortunes out of them. In fact, we do the same thing ourselves here. When a new stock comes on the board, it is bought up on general principles without the buyers ever knowing or caring where or what it is as long as they see a chance of profit and can buy at hedrock prices. The Eastern people who see on the certificates, "Capital stock \$5,000, 000 in 50,000 shares of \$100 each," think they are getting the stock cheap when they pay \$10 per share; but we here know that this kind of stock, "par value \$100," is often sold for ten cents per share, when it is "hedrocked" on the market.

We know, moreover, that thousands of shares of stock which have no value whatever are floating about the country. The stock of companies which have failed or temporarily abandoned work, or had the sheriff take possession, or have otherwise "busted," is apparently good. It is not cancelled or destroyed, and when unscrupulous parties have this kind of stock and go to a region where they can put on wise looks and use a few mining terms, they stand a pretty good chance to dispose of it to credulous individuals.

There is scarcely any way to guard against these practices, and the people of the Eastern States have been pretty heavy sufferers from them from time to time. It has worked great injury to the mining interests without doubt, as those who have been "bitten" take good care to warn others, and really meritorious enterprises have been made to suffer. If people in the East desire to engage in the laudable venture of mining enterprises, and would do so intelligently, let them subscribe for and carefully consult the *MINING AND SCIENTIFIC PRESS*, in which every mining enterprise worthy of mention is noticed from time to time. A mining enterprise of the Pacific coast which is not referred to in this journal in some way or another, as often as once in three or four months, is certainly one which people in the Atlantic States should beware of. Moreover, we are willing to furnish such information as is in our power to all our subscribers concerning mining enterprises. Even here we cannot readily guard against "wildcat companies," but we can tell whether any certain company is still in existence and whether its mine is being worked or not. Our Mining Summary contains notices of mines weekly, from all sections of the coast, and we can generally find out something concerning any special mine about which information is desired. This warning is particularly timely just now, when so much interest is manifested by people east of the mountains in the mining resources west of them.

End of Volume XXXII.

Again the march of time has brought us to the end of a volume, this being the last issue of Volume XXXII of the *MINING AND SCIENTIFIC PRESS*. The copious, although condensed, index on the last page of this issue, shows the variety and scope of the contents of the 26 papers which have made up the volume, and speaks more for the value which we give for the price of a year's subscription than we can say in this connection. As a new volume begins with the next issue, we take occasion to suggest that it is a good time to subscribe. While there is every reason for gratification at the circulation which this journal has reached, we are yet well aware that there are numbers of miners, mechanics and lovers of science to whom it might be made a source of much usefulness and profit. We feel no hesitation in urging the claims of the paper upon the attention of all for whose special benefit it is published. Having a circulation among special classes and the most intelligent and thriving portion of our people, it presents a very valuable medium for advertising—a feature which

our columns show for themselves, is quite generally appreciated.

We take occasion also to remind many of our old subscribers and readers that communications of a character suitable to this journal are always acceptable. We are pleased at all times to hear of anything new in mining or mechanics, and will take every care that due credit is given to the writers. Those who are engaged in practical work have so many opportunities for observation that they should impart their increasing knowledge to others. Every branch of trade has its peculiarities and its varying improvements, and those who have an opportunity of observing them should not hesitate to assist others. This paper is a proper channel for such communications, and we desire to encourage correspondents. If any of our readers who have the inclination to write but are only deterred from so doing because they fear that their literary efforts may not equal their mechanical, will send in their articles, we will take pains to arrange them properly for publication.

Again we say this is a good time to subscribe. No miner or mechanic should be without a home paper devoted to their interests. Hints and suggestions of infinite value to all classes of mechanics and miners are constantly being published, and we are careful to glean from all sources whatever will be useful to our subscribers. The *MINING AND SCIENTIFIC PRESS* is read in every mining camp west of the Rocky mountains, and it is the duty as well as the pleasure of its editors and proprietors to make it a welcome weekly visitor. We propose to continue to improve the Press and make it even more valuable and interesting to miners and mechanics than ever.

The Mechanics' Institute Fair.

Active preparations for the eleventh industrial fair, under the auspices of the Mechanics' Institute, continue to be made. The managers are holding frequent meetings for the purpose of perfecting arrangements for the exhibition, which it is hoped will excel others previously given. To those who are unable to attend the great Centennial exposition this fair will be an excellent substitute, and will, no doubt, be appreciated as such by our citizens.

The fair will open on the 8th of August, and continue for not less than 30 days, nor more than 35 days. The number of exhibitors will be larger than usual, and many new features are to be introduced. Among other things a special effort will be made to make the music of the next fair a prominent feature, and it is suggested by the Committee on Music that more than one band be employed for this purpose. The Committee on Location have been instructed to prepare a plan of the floor with the proposed changes. The Committee on Decorations have under advisement a plan to increase the number of fountains by putting two at each end of the building. They intend also to enlarge the space around the central fountain, and place within the railing a number of flowers and shrubs.

At a meeting of the Board of Managers this week, the chairman of the Committee on Power and Machinery reported that the Fulton foundry was constructing for the exhibition a very powerful and highly finished engine to drive the machinery at the fair. The Union foundry and other foundries were also engaged in preparing special machinery for exhibition. He also reported that there were at this time a large excess of applications for space over that of the last fair, and that there is every certainty of having a full representation of the industries of the State and productions of its soil at the coming exhibition.

The President, Vice-President and Treasurer were appointed a committee to confer with the Art Association in regard to the Art department of the fair.

The gardener reported that the garden was in excellent condition. He recommended that the Horticultural Committee confer with the various florists and fruit growers, with a view of obtaining a full display of the fruit and flowers, which on motion was passed.

The Superintendent reported that the Wine Growers' Association propose to exhibit largely at the next fair.

The Building Committee was instructed to submit a specification of work for removing the seats and for alterations on the building necessary to be made, and submit it to the next meeting of the Board.

The President announced the following committees to take charge of the affairs of the forthcoming exhibition: Auditing—Hayes, Spaulding, Browning. Building—Drury, Wells, Smith. Circulars and Classification—Browning, Spaulding, Stoutenborough. Printing and Advertising—Spaulding, Cornwall, Patrick. Power and Machinery—Smith, Spiers, Elliot. Rules and Regulations—Patrick, Davis, Elliot. Tickets and Admission—Wells, Stetson, Cornwall. Music and Decorations—Davis, Smith, Stoutenborough. Privileges—Cornwall, Stetson, Wells. Location—Spiers, Drury, Hayes. Police—Stetson, Hayes, Patrick. Horticultural Garden—Stoutenborough, Davis, Drury. Gas and Water—Elliot, Spiers, Browning.

We propose, as usual, to give in the Press full reports of such matters as are of interest to our special classes of readers.

How Valuable Mines Should be Recognized, Prospected and Worked.

[For the Press by E. G. G.—No. 4.]

About the places where gold is generally found, we have remarked that it appears mainly in ledges of whatever nature they may be, but in country rock of primary period, such as syenite, slate, gneiss, etc., also in debris and the gravel of river beds.

It is estimated that the yearly production of gold in the world amounts to 400,000 pounds.

2. Silver Ores.

The varieties of silver ores are manifold; we will, though, for the sake of shortness, only consider the nine most prominent ones, which may, even by the uninitiated in mineralogy, be readily recognized.

A. Native Silver.

Color, metallic white; shows sometimes yellowish or grayish. Specific gravity 10.4. Dissolves readily in nitric acid and the solution containing nitrate of silver, if put on to the skin, causes a black mark. It generally contains traces of copper, iron, gold, etc.

B. Argeitile.

Color, dark leadish; scratch shining. It can be cut like lead, smelted with soda and is easily dissolved in concentrated nitric acid, sulphur precipitating. Composition: silver 87.1, sulphur 12.9. Specific gravity 7. It has the appearance of smelted lead or as though it was eaten out by constant action of an acid; sometimes it is found wiry.

C. Stephanite.

Color, iron black or lead gray. Specific gravity 6.3. It is easily dissolved in nitric acid. Caustic potassa takes up sulphide of antimony which, when the solution is neutralized, drops in brown flakes. Composition: silver 71.01, sulphur 15.80, antimony 13.19.

10. Proustite (Light Ruby Silver).

Color, cochineal to carmesine red, like a ruby. Specific gravity 5.5. If boiled for some time in solution of caustic potassa, sulphide of arsenic is extracted, which, upon hydrochloric acid being added, precipitates in yellow flakes.

E. Pyrargyrite (Dark Ruby Silver).

Color, carmesine red to dark lead gray; on the edges transparent; scratch carmesine red. Specific gravity 5.8. If treated with caustic potassa, sulphide of antimony is extracted; hydrochloric acid being added precipitates in brown flakes.

F. Kerargyrite (Horn Silver, Chloride of Silver).

Color, greasy, shining pearl gray, grayish white. Can be scratched by the finger nail, leaving a shining mark. Specific gravity 5.5. If melted on charcoal in the oxide of copper it imparts to the flame a fine blue color. Composition: silver 75.25, chlorine 24.75.

The Sutro Tunnel Decision.

The history of the Sutro tunnel, and the nature of the claim of the tunnel company against the mining companies whose claims are located upon the Comstock lode, are tolerably familiar to most of the people of this coast who are interested in the Nevada mines. According to the terms of the original agreement with Adolph Sutro, he was to receive a royalty of two dollars per ton for all the ore extracted from the mines on that lode after the completion of the tunnel. A recent decision of the U. S. Land Office was adverse to the tunnel company, and now Judge Dwinelle, of the 15th district court, has rendered a decision upon a demurrer to the complaint in the case of the Crown Point company against the Sutro tunnel company. The demurrer was overruled. One of the conditions upon which the payment of this royalty was predicated was that the tunnel should be completed within eight years from the signing of the contract. The stipulated time elapsed and the tunnel was not finished. The Crown Point company, considering Sutro's claim as a cloud upon the title of the mine, brought suit for the purpose of finally settling any question that might arise out of the old contract.

The decision is quite lengthy and covers considerable ground. The concluding paragraph, which is as follows, takes the ground that the Sutro contract is a lien:

"That this court has jurisdiction in a proper case to declare a deed or an agreement a cloud upon the title to real property is fully established by the above authorities. That the agreement set forth in the complaint is an instrument which, if *functus officio*, casts a cloud upon the title of the plaintiff's mine, will not be disputed. The agreement is in effect a mortgage on its face. It is a specific lien in equity, and such liens are by courts of equity treated and considered as mortgages. Daggett vs. Rankin, 32 Cal. 321."

"It has been recorded in the proper court as a lien. If still in force, after default, it could be foreclosed as such. The allegations of the complaint, taken as true, show the agreement has ceased to be obligatory upon the plaintiff, and that it is a cloud upon the plaintiff's title to its mine, and that it should be surrendered and canceled."

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency the following are worthy of mention:

DRILL SOCKET.—Charles Allison, S. F. This invention relates to an improved socket head for holding drills and other tools which are subjected to a twisting strain under pressure. The inventor provides a tool holder in which a cylindrical tool shank can be securely held, thus enabling him to form a tool point on the end of a piece of rod steel and use it as a drill or other similar tool without altering the form of its shank. This tool holder will hold cylindrical shanks against torsion and thus save much time and labor in forming the shanks of drills to adapt them to be held with the requisite tenacity.

LUBRICATOR.—James M. McDonald, S. F. This invention relates to certain improvements in the construction and application of that class of devices for supplying a lubricant to the journals of railway axles, in which the lubricant is raised through a wick by capillary attraction and supplied to a pad of absorbent material, said pad being supported by a spring in such a manner that the saturated absorbent material will be kept in contact with the journal for the purpose of supplying it with a uniform quantity of oil. These lubricating devices consist essentially of a pad composed of an absorbent material, a pad holder for supporting the pad and holder and a wick for supplying oil to the pad. A number of patents have been issued on the various methods of arranging and adapting these parts in order to produce a successful lubricating device, prominent among which are the patents issued to Ernest Von Jeison at various dates in the year 1870, and while these patented devices combine the elements of success, the manner of their combination and application has not been such as to render them sufficiently complete for continued practical use. By Mr. McDonald's construction of the lubricating device he adapts every part in an easily constructed and economical manner, and so as to avoid the difficulties heretofore encountered with this class of lubricators.

HARROW.—Ezra M. Stevens, Santa Rosa, Sonoma county, Cal. The inventor calls this the Athletic harrow on account of its great flexibility and the ease with which it can be managed in order to clear it from the accumulations of weeds and avoid obstructions while it is working, and the facility with which it can be raised clear of the ground when being moved from field to field. This harrow is flexible in every direction. The driver can, without leaving his seat, lift any portion, so as to clear it from weeds, or he can raise the entire harrow so that the wheels alone will bear, and thus permit it to be drawn along a road. The entire harrow arrangement is quite effective and simple and can be handled with great ease. It can be converted into a simple harrow by removing a portion of it and attaching the remainder together. The trucks and seat can easily be removed, so as to convert it into a walking harrow, and in packing it for transportation it can be taken entirely to pieces and packed into small compass.

IMPROVEMENT IN PLOWS.—G. J. Overshiner, San Jose. Various devices have hitherto been employed to secure the share to the mold board of plows in such a manner as to allow it to be removed; among others the use of dovetailed tongue and slots, either made in a line with the joint, or in some cases transversely to it. These are open to the objection that they have easily become rusted or otherwise rendered immovable by the warping and changing of shape in the share when sharpened by hammering it, so that the points will no longer fit. In this invention Mr. Overshiner fits the share to the mold board with a plain joint, and provides two lugs upon the share which fit into shallow recesses provided for them upon the back of the mold board and between it and the land-side, and these, with an upward projecting lug or point upon the share, serve to hold the parts in place, while the single hook-bolt draws all the parts firmly together. By this means adjustable or removable plow shares are secured to the mold board so that they can be easily removed for the purpose of sharpening.

SUSPENSER BELT FOR FEMALES.—Edwin J. Fraser, S. F. This invention relates to an improved hip belt or band for supporting stockings, suspenders and other appendages from the waist of females, the object being to so construct the belt or band that it will conform to the shape of that portion of the body upon which it is supported, so that the strain or pull upon it will be received upon and over the hips instead of dragging upon the waist in the manner of the ordinary waistband. Dr. Fraser calls his invention a "conformation waist band."

SCREW PLATE.—J. S. Campbell, Astoria, and Thomas T. Eyre, Salem, Oregon. The object of the invention is to so arrange and apply the dies in a screw plate that they can be set to cut threads of any desired size, and so that when the dies are once set they will cut a screw of uniform size so that the same nut will fit every screw made by it.

McCall's Road Grader, Ditch and Levee Machine.

We give on this page an engraving of a machine which has come into wide favor because of its useful and effective work. It has been proved in all its lines of work. As a machine for road making it is worthy of consideration from the fact that the supervisors of five counties, Santa Clara, San Mateo, San Benito, Monterey and Santa Cruz, have purchased it for road work in their counties after full examination of its merits. As an instance of its road making, Moses Davis of the Davis & Chapman tract, states that he graded five miles of streets in 11½ days with 10 horses and two men, without plowing. It was in the month of August in dry, hard adobe. In ditch and levee making it has been used on Roberto's island, near Stockton, by Mr. J. P. Whitney and pronounced most successful. On railroad work Messrs. Turtin & Knox, of Sacramento, state that the machine is equal to 90 men with shovels or 40 horses and 26 men with hand scrapers. We present this evidence to show the character of the machine.

In addition to the above we would mention that Mr. McCall's apparatus took three premiums at the last State fair, one in each branch of its work, viz: one as an open ditch plow, one as a ditch and levee machine and one as a farm and road scraper. A contest before a committee of supervisors and citizens at

FAULKNER'S EXCELSIOR FAMILY FRUIT DRIER.

Stockton last year resulted in Mr. McCall's favor.

This machine, as shown by the engraving, consists of one main beam, supported by four strong iron flanged wheels, with peculiar and ingeniously contrived axletrees, which, by means of a ratchet lever, are adjusted so as to set the wheels bracing and tipped to any desired pitch, either to the right or left, thereby counteracting all side pressure. The mold board or blade is all made of steel, 17 inches wide and 10 feet long, including a shear like that of a plow, deeply concaved. This blade is supported under the main beam, and attached by connecting rods and levers to a turn table on top of the beam, so as to be lowered or raised at will, or turned at any desired angle,

McCALL'S ROAD GRADER.

throwing a furrow either to the right or left, or square with line of travel.

For grading uneven land, cutting off the high places and depositing its load in the low, the center of the blade is pivoted on a V shaped push bar, the wide ends of which are strongly hinged to a false bolster, or cross timber, near and just in front of the hind axle. This main push bar holds the blade from being moved sideways by any pressure of earth against it, but allows it to raise or lower, as desired. The turn-table on top of the beam turns always with, and at the same angles of the blade, and forms a platform on which the operator stands to regulate the working of the machine. It may be worked with four horses, and as many as 20 have been used, but usually 10 or 12 horses are employed. Information concerning the machine may be obtained by addressing the McCall road grader, ditch and levee machine company, at San Jose, Cal.

Faulkner's Excelsior Family Fruit Drier.

We take pleasure in calling the attention of our readers this week to another candidate for public favor: Faulkner's Excelsior portable family fruit drier. The public have long called for a low priced economical fruit drier, one with which the fruit grower can save their surplus fruit and convert it into money or its equivalent, trade at the store. The Excelsior drier, it is claimed, will turn out goods equal in quality to any other drier.

The Faulkner family drier has one great advantage in being very low priced: \$65 to \$75, with more drying surface than some others costing much more. It is plain and durable in its construction and very simple in its management. By watching the thermometer in the front part they can regulate the heat accurately by closing the lower registers and shutting off the heat, or opening the top ones let the heat escape. By use of the reserve hot air chamber the heat can be forced into any part of the drying chamber requiring it, thus drying the fruit equally in all parts of the chamber. By this arrangement one of the main objections to fruit driers where the trays are one above the other is overcome. By the use of the reversible trays the fruit can be turned in a moment without handling it. The reserve hot air chamber

and reversible trays are advantages possessed by no other drier.

The Excelsior drier is made portable, being mounted on rollers, and is easily moved from place to place. It can be run in the house or out of doors. It can be used in connection with the ordinary cook-stove or any small stove. When not in use can be used as a safe for provisions, or as a refrigerator. It is made very compact, the lower part holding the upper part when you wish to store it away. Mr. Faulkner had his drier in operation in Auburn, Placer county, during the winter of 1874-5. It received the approval of the principal fruit growers and residents there. The sale of the drier is in the hands of the leading houses in their lines in many of the cities East. It is manufactured for the Eastern States by Messrs. Jes. L. Lockwood & Co., Stamford, Conn., and by Mr. E. T. Steen, 236 to 232 Beale street, San Francisco, for California, etc. County rights and information of all kinds concerning the drier can be had of the inventor, J. W. Faulkner, 31 Beale street, S. F.

VOLATILIZED GOLD.—At the last meeting of the San Francisco microscopical society, Geo. Hewston donated a slide mounted with volatilized gold, which under a two-third objective, opaque, was not only a beautiful but instructive object. The microscopic globules were perfect in shape, and were obtained at some distance from the melting pot, from which they had been thrown off by the draft and heat in a volatile form, so to speak, and condensed in the air in the form of minute shot, forming a veritable shower of golden rain. With all the care and appliances for the prevention of waste in smelting or refining gold, a portion is lost in this way, and no doubt the roofs of the houses adjacent to smelters and refineries would yield enough of the precious metal to show the color, at least, under the microscope.

The Tribune Washington correspondent draws a startling picture of what may be the result if the appropriation bills are not finally passed by both houses in less than ten days. The features are that our Ministers and Consuls abroad will be recalled, the army annihilated, and the postal service stopped.

GEM AND PRECIOUS STONES.—Mr. Hanke's continued article on this subject is unavoidably deferred this week, but will appear in the next issue.

The usual clean-up of 400 ounces of gold amalgam was made at the Eureka mine, Grass valley, last week.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORT FOR THE MINING AND TITVIO PRESS, DEWEY & CO., PUBLISHERS, SOLE U. S. AND FOREIGN PATENT AGENTS, 117

FOR WEEK ENDING JUNE 6TH, 1876.

General News Items.

BRISTOW'S resignation has been formally accepted.

A \$40,000 fire occurred in Virginia City on the 19th inst.

SENATOR MORRILL will leave his place in the Senate to take charge of the Treasury Department on the 1st of July.

REPORTS of enthusiastic Hayes and Wheeler ratification meetings come from various quarters.

THE President has nominated James A. Williamson of Indiana to be Commissioner of the General Land Office.

THE Bay sugar refinery, in this city, was destroyed by fire on Monday night. Loss, \$400,000. The refinery will be immediately rebuilt.

SAMPSON, the North Adame (Mase.) shoe manufacturer who has employed Chinese for the past few years, has decided to discharge them and substitute white workmen.

A DISPATCH from Berlin says that one captain and six lieutenants of the Chinese army have arrived there, accredited by China, and bearing a request to be allowed to serve in the Prussian army for the purpose of studying the German military system. The request was granted.

THE Sheffield Telegram says: A further reduction of 12½ per cent. in miners' wages in the West Riding of Yorkshire is about to be made, and it is thought it will be accepted by the men. The secretary of the miners' union has written to all the miners' lodges that "we are on the eve of a terrible crisis, and that there must not be a strike, but terms must be made somehow." He assures them that if a strike is begun there is every possibility of its failing, with the possibility of having to submit to still greater reduction.

THE Bank of Nevada County, at Nevada City, has encumbered. Some three or four months since its doors were closed, and the usual clamor among creditors was indulged in. The managers felt confident that the institution would be in a condition to resume, and the excitement was for a time allayed. The 16th of the present month was named as the day upon which the doors of the bank would be thrown open. The President has published a card stating that it will be impossible for the concern to resume, and that an assignment in full of the effects has been made to a responsible party for the benefit of the creditors.

MINING ENGINEER.

All classes of mining properties reported on, consultations had on reduction of ores of all descriptions, plans for furnaces and reduction works furnished, and the construction of them superintended. Ore tests made at the office,

306 Front St., Cor. California, S. F.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.) Our new Mining Engine is built from plans and specifications of several of our most successful MINING ENGINEERS, and the result is the most complete

Double Drum Hoisting Engine

Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

BERRY & PLACE,

(Successors to Treadwell & Co.)

Hoisting Engines, Diamond Pointed Rock Drills,
Manufactured by M. C. BULLOCK,

SODIUM AMALGAM.

I am prepared to furnish Sodium Amalgam for \$1.50 per pound. Although the price is low, my reputation is a guarantee of its purity. Sodium being now much cheaper than formerly, the miner and millman should have the advantage of it. The temptation to adulterate the article being so great, consumers are advised to call for my manufacture when ordering from wholesale dealers, with an assurance on my part that the quality will be the best. Zinc is sometimes substituted for sodium, to the great disadvantage of the consumer. The following are the tests for pure Sodium Amalgam: Shaken up with water it must be wholly decomposed, the mercury remaining perfectly fluid and the water becoming strongly alkaline.

HENRY G. HANKS,
619 Montgomery Street, San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

\$5 to \$20 Per Day at home. Terms free. Ad-
dress G. STIMPSON & CO., Portland, M.

The ALLEN ENGINE GOVERNOR.

Uniform Speed in the Working of Steam Engines.

THE SIMPLEST AND MOST EFFICIENT GOVERNOR YET CONSTRUCTED.

ECONOMY and SAFETY.

Especially Valuable with Adjustable Cut-Offs. Capacity of Machinery Increased by Accurate Regulation of Speed.

Direct Saving of Fuel—Great Increase in Power of Engines.

The high rate of speed used acts advantageously in making the Allen Governor very sensitive; and all parts being lubricated, it works with the smallest amount of friction.

The speed of the Engine is maintained equally, without reference to the variations in amount of work being done.

The peculiar action of the Governor, which allows the use of a valve of large area, thereby admitting to the Engine cylinder the greatest possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Allen's Patent Governor Valve is constructed with a double disc in a tubular frame, and is perfectly balanced, there being no spindle as in the ordinary throttle valve to interfere with its equilibrium. The valve is moved by means of a lever, and is opened and closed by a rocking motion of a steel spindle, which is covered with brass, insuring the greatest possible durability.

Fig. 1. For Variable Cut-Off Engine

possible boiler pressure at each stroke of the piston, has produced astonishing results by being attached to old engines, greatly increasing their power or effecting a direct saving of fuel, and in hundreds of instances doing both. In running an engine with the Allen Governor with high or low pressure of steam and with all variations of power, the throttle is opened wide in the morning and remains so until closed at night, thus relieving the engineer from all labor and care except keeping the engine oiled, and giving him a great deal of time for other duties.

Fig. 2. Allen Governor and Valve.

We have Numerous testimonials from parties who have used this Governor, and watched its workings critically. In all cases the Governor has made the various engines to which it has been applied produce the most profitable results ever obtained.

Fig. 3. Section of Allen Governor.

PARTIES INTERESTED IN STEAM MACHINERY SHOULD EXAMINE THE ALLEN GOVERNOR, WHICH IS NOW INTRODUCED ON THIS COAST FOR THE FIRST TIME. FULL INFORMATION CONCERNING IT CAN BE OBTAINED FROM ILLUSTRATED DESCRIPTIVE CIRCULARS, WHICH WILL BE SENT ON APPLICATION. Address,

PACIFIC IRON WORKS, First and Fremont Streets, near Howard, San Francisco, MANUFACTURERS OF ALL CLASSES OF MACHINERY.

Machinery.

The Ingersoll Rock-Drill

Is Extensively Used in the East and TAKES THE PLACE OF ALL OTHERS.

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and HAS AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

11th Industrial Exhibition,

Under the Auspices of the
MECHANICS' INSTITUTE.

The managers have the honor to announce that the forthcoming Exhibition will be opened to the public on

Tuesday, August 8th,

At 11 A. M., with the usual ceremonies. By the desire and co-operation of the leading citizens of San Francisco, the Exhibition will be held on a much grander scale than heretofore.

The Exhibition Building, Occupying an Area of over 100,000 Feet

Of floor room, will be completely filled with the varied products of the skill and industry of the people and of the soil. Over 700,000 persons were admitted during the last Fair. The managers intend to engage the services of the best instrumental talent of the country, so as to enable them to give unequalled

Musical Concerts After-noon and Evening.

In every department applications for space far exceed expectations, and surpass those of former Fairs. Intending exhibitors must not delay filing their applications, otherwise they will be excluded.

The Exhibition will continue at least one month. There will be no charge for exhibiting space.

Application for space or for information should be addressed to the Secretary of the Board of Managers, Eleventh Exhibition, 37 Post St., San Francisco, or to J. H. Gilmore, Supt., at same address.

A. S. HALLIDIE, Pres't.

J. H. CULVER, Sec'y.

No bills will be paid by the Managers unless ordered by the proper committees.

In United States gold and silver coin, to the Secretary at his office, 60 Montgomery street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-first day of June, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the sixth day of July, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

SAMUEL S. MURPHY, Secretary.

Office, 60 Montgomery street, San Francisco, Cal.

Umpire Tunnel and Mining Company of Utah.

At a Directors' meeting of above company, held on the 16th inst., it was resolved that a meeting of stockholders of the company be convened on Monday, June 19th, 1876, at the office of the company, 635 California street, to decide upon a proposition to increase the capital stock of the company from three hundred thousand (\$300,000) dollars, divided into thirty thousand (30,000) shares of ten (10) dollars each, to seven hundred and fifty thousand (\$750,000) dollars, divided into seventy-five thousand (75,000) shares of ten (10) dollars each.

(Signed) R. R. HARRIS, W. W. DAVIS, T. E. HUGHES, E. McPHERTRIDGE

NEAR MISSION & HOWARD, - - - SAN FRANCISCO.

HENDY & COCHRANE'S ORE FEEDER

FOR QUARTZ MILLS,

AWARDED FIRST PREMIUM AT THE TENTH INDUSTRIAL FAIR OF THE MECHANICS' INSTITUTE.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane, or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says, of the Table Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. O. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Mr. Lachman, of the Soulsby Mill, Tuolumne County, says they work splendidly; could not do better. Two of the machines were shipped to the California Company, Nevada City. C. J. Garland, of Mosquito Gulch, Calaveras County, says: "I find them an excellent machine." S. D. B. Stewart, Supt. Lincoln Gold Mining Company, says they are a perfect success. O. C. Hewitt, Supt. Keystone Mining Company, says: "I can safely recommend them to all millmen."

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other machine of its class.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS.

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.
